SPONSORED RESEARCH OR DEVELOPMENT

This invention was made with government support under CA109010 awarded by the National Institutes of Health. The government has certain rights in the invention.

BACKGROUND OF THE INVENTION

I. Field of the Invention

The present invention relates generally to the fields of protein chemistry and developmental biology. More particularly, it concerns peptide segments from the extracellular domain of syndecan-1 (Sdc-1) that can inhibit angiogenesis and can thus be used to treat angiogenesis in pathologic conditions.

II. Description of Related Art

A. Function of αβ3 and αβ5 Integrins in Angiogenesis

Several different growth factors, among them fibroblast growth factor (FGF) and vascular endothelial cell growth factor (VEGF), are often released by tumors to cause endothelial cells to undergo angiogenesis. Blood vessels in the vicinity of the tumor respond to VEGF by becoming leaky (thus the alternate name “vascular permeability factor”) allowing fibronectin, vitronectin and fibrinogen in the blood to infiltrate the surrounding matrix. These matrix ligands are critical adhesion and activation ligands for the αβ3 integrin, which have roles in the chemotactic migration of the endothelial cells and in the survival of the cells during vessel pruning. A second response to the growth factors, particularly FGF, is the activation of a neovessel development program that relies on Hox master genes (Boudreau et al., 1997; Myers et al., 2000; Myers et al., 2002). HoxD3 is initially expressed and controls a family of genes that are necessary for the initial migration process, including upregulation of the αβ3 integrin, MMPs and uPAR (Boudreau et al., 1997). Expression of HoxD3 is followed by HoxB3, which regulates the morphogenesis leading to the formation of small vessels (Myers et al., 2000), and finally by the HoxD10 gene, which restores the mature phenotype of the cells (Myers et al., 2002); it is HoxD10 that is expressed in resting, stable blood vessels in vivo.

The αβ3 and αβ5 integrins are important not only during endothelial cell migration, but are important players in the survival of the endothelial cells. Although endothelial cells in mature vessels are not readily susceptible to apoptosis, angiogenic cells that are induced by growth factors are highly susceptible and rely upon the continued presence of these factors for survival. This is shown experimentally by inducing angiogenesis with VEGF and causing apoptosis by its withdrawal, and is demonstrated in vivo when the developing ovarian follicle induces angiogenesis by release of VEGF and the newly formed blood vessels regress when the source of VEGF is lost upon ovulation. Endothelial cells responding to VEGF rely on signaling from the αβ5 integrin in order to prevent this apoptotic process (Brooks et al., 1994; Friedlander et al., 1995). Similarly, endothelial cells responding to fibroblast growth factor (FGF) are susceptible to apoptosis unless there is coordinate signaling from the αβ3 integrin. Thus, inhibitors that disrupt the activation of these two integrins are potential drugs for blocking angiogenesis not only because they can prevent the positive signaling from the integrins that aid in endothelial cell migration and formation of new vessels, but also because they have the potential to elicit “negative” signals that trigger apoptosis and death of the endothelial cell. Furthermore, this mechanism is not confined to endothelial cells and would apply as well to tumor cells or other cells that rely on either of these integrins to initiate disease processes.

B. Syndecans

The syndecan family of cell surface heparan sulfate (HS) proteoglycans is comprised of four vertebrate members. These receptors are expressed on virtually all cell types, although their expression may be altered in disease states such as cancer (Beauvais and Rapraeger, 2004). The syndecan core proteins share a high degree of conservation in their short cytoplasmic and transmembrane (TM) domains; in contrast, their ectodomains (EDs) are divergent with the exception of attachment sites for HS glycosaminoglycans. Via their HS chains, syndecans regulate the signaling of growth factors, chemokines, and morphogens and engage components of the ECM including VN, FN, LN, tenascin, thrombospondin, and the fibrillar COLs (Bernfield et al., 1999).

In addition to the activities of their HS chains, the syndecan core proteins have roles in cell adhesion signaling (Rapraeger, 2000; Tumova et al., 2000). Conserved and variable regions of the syndecan cytoplasmic domains appear critical for binding interactions that lead to adhesion-mediated signaling and reorganization of the actin cytoskeleton (Couchman et al., 2001). Important roles for the TM domain have also been demonstrated for Sdc-1 and syndecan-4 (Sdc-4) (Tkachenko and Simons, 2002; McQuade and Rapraeger, 2003). Perhaps the least expected active protein domain is the syndecan ED, which bears the HS chains. Nonetheless, several emerging studies suggest that the syndecan ED may have important regulatory roles in cell adhesion signaling. Cell spreading and morphogenetic activities in COS-7 and Schwann cells trace in part to the S1ED (Carey et al., 1994; Adams et al., 2001). Raji cells require the Sdc-1 TM domain for initial spreading, but depend on a S1ED activity for cell polarization (McQuade and Rapraeger, 2003). Moreover, inhibition of ARH-77 myeloma and hepatocellular carcinoma cell invasion into a COI I matrix by Sdc-1 also traces to a region of its extracellular core protein domain (Liu et al., 1998; Ohtake et al., 1999).

The activities of other syndecans also trace to their EDs. Overexpression of Syndecan-2 (Sdc-2) in COS-1 and Swiss 313 cells induces filipodial extension and deletion mutants of Sdc-2 map activity to the S2ED (Granes et al., 1999). Upregulation of Sdc-2 expression in colon carcinoma cells leads to altered cell morphology and colony formation in soft agar; treatment with recombinant S2ED disrupts these behaviors (Park et al., 2002; Kim et al., 2003). Finally, activated B-lymphocytes, when seeded on S4ED antibodies, exhibit morphological changes and filopodial extensions. Intriguingly, only the S4ED is required for this response,
indicating that it may interact with a TM partner to transmit a dendritic signal (Yamashita et al., 1999).

C. αβ₃ Integrins are Regulated by Syndecan-1

The inventors’ previous work in the MDA-MB-231 cells suggested that cell spreading induced upon anchorage of the cells to an Sdc-1 antibody relies on functional coupling of the syndecan to activated αβ₃ integrins (Beauvais and Raepraeger, 2003). This spreading response is rapid (~15-30 min) and occurs even in the absence of an integrin ligand (i.e., spreading is not blocked by cycloheximide or EGF treatment), so long as the cells are adherent via Sdc-1. Intriguingly, the αβ₃-dependent spreading mechanism is blocked by the addition of soluble, recombinant Sdc-1ED, suggesting that anchorage of Sdc-1 to a ligand provides a platform for αβ₃ integrin activation and adhesion signaling via binding interaction of the syndecan ED. These findings raised a fundamental question about the role of Sdc-1 in ECM signaling, in particular whether or not Sdc-1 is required for αβ₃ activation and signaling in response to a native matrix ligand. The inventors went on, in subsequent studies to show that Sdc-1 is required for signaling through both αβ₃ and αβ₅, and that inhibition of this function by competitive binding (Sdc-1ED) or siRNA inhibition blocks cell attachment, cell spreading, cell migration and angiogenesis (unpublished).

SUMMARY OF THE INVENTION

Thus, in accordance with the present invention, there is a provided an isolated and purified peptide or polypeptide segment consisting of between 5 and 100 amino acid residues and comprising SEQ ID NO:21 or SEQ ID NO:13. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28, that is, the peptide differs from SEQ ID NO:28.

It is specifically contemplated that any embodiment relating to a peptide or polypeptide of the invention may be implemented in any other embodiment of the invention, including in methods of the invention.

In another embodiment, there is provided a nucleic acid encoding a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues and comprising SEQ ID NO:10. The nucleic acid may encode a peptide or polypeptide of 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, or 100 amino acid residues in length, or any range derivable therein. The nucleic acid encodes a peptide consisting of SEQ ID NO:10. In other embodiments, the nucleic acid encodes a peptide consisting of or comprising SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28.

In yet another embodiment, there is provided a recombinant cell comprising a nucleic acid encoding a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues and comprising SEQ ID NO:21 or SEQ ID NO:13, or any amino acid segment discussed above. The cell may be a bacterial cell. The cell may comprise a nucleic acid further encoding a peptide tag fused to the nucleic acid encoding said peptide segment.

In still yet another embodiment, there is provided a pharmaceutical composition comprising an isolated and purified peptide or polypeptide segment consisting of between 5 and 100 amino acid residues and comprising SEQ ID NO:21 or SEQ ID NO:13 (or any amino acid segment discussed above) dispersed in a pharmaceutically acceptable buffer or diluent. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28.

In a further embodiment, there is provided a method of inhibiting interaction of αβ₃ or αβ₅ integrin with syndecan-1 comprising contacting a αβ₃ or αβ₅ integrin molecule with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising SEQ ID NO:21 or SEQ ID NO:13. The peptide or polypeptide may be 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, or 100 amino acid residues in length, or any range derivable therein. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28.

In yet another embodiment, there is provided a method of inhibiting αβ₃ or αβ₅ integrin with syndecan-1 comprising contacting a αβ₃ or αβ₅ integrin molecule with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising SEQ ID NO:21 or SEQ ID NO:13. The peptide or polypeptide may be 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100 amino acid residues in length, or any range derivable therein. In yet another embodiment, there is provided a recombinant cell comprising a nucleic acid encoding a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues and comprising SEQ ID NO:21 or SEQ ID NO:13, or any amino acid segment discussed above. The cell may be a bacterial cell. The cell may comprise a nucleic acid further encoding a peptide tag fused to the nucleic acid encoding said peptide segment.

In still yet another embodiment, there is provided a pharmaceutical composition comprising an isolated and purified peptide or polypeptide segment consisting of between 5 and 100 amino acid residues and comprising SEQ ID NO:21 or SEQ ID NO:13 (or any amino acid segment discussed above) dispersed in a pharmaceutically acceptable buffer or diluent. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28.

In a further embodiment, there is provided a method of inhibiting interaction of αβ₃ or αβ₅ integrin with syndecan-1 comprising contacting a αβ₃ or αβ₅ integrin molecule with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising SEQ ID NO:21 or SEQ ID NO:13. The peptide or polypeptide may be 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100 amino acid residues in length, or any range derivable therein. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28.
embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28. The peptide or polypeptide may be 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length. The peptide or polypeptide may consist of SEQ ID NO:1. In other embodiments, the peptide may consist of or comprise SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28. The inhibiting may result in inhibition of cell adhesion, migration, cell metastasis, cell survival and/or cell proliferation.

In still yet a further embodiment, there is provided a method of treating a subject with a cancer, cells of which express α5β3 or αβ3 integrin, comprising contacting said cells with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising SEQ ID NO:21 or SEQ ID NO:13. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28. The peptide or polypeptide may be 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length. The peptide or polypeptide may consist of SEQ ID NO:10. In other embodiments, the peptide may consist of SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28. The subject may be a human. The cancer may be a carcinoma, a myeloma, a melanoma or a glioma. The peptide or polypeptide may be administered directly to said cancer cells, local to said cancer cells, regional to said cancer cells, or systemically. The method may further comprise administering to said subject a second cancer therapy such as chemotherapy, radiotherapy, immunotherapy, hormonal therapy, or gene therapy.

In an additional embodiment, there is provided a method of inhibiting angiogenesis comprising contacting an endothelial cell expressing an α5β3 or an α5β3 integrin, comprising contacting said cells with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising SEQ ID NO:21 or SEQ ID NO:13. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28. The peptide or polypeptide may be 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length. The peptide or polypeptide may consist of SEQ ID NO:10. In other embodiments, the peptide may consist of or comprise SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28. The subject may be a human. The cancer may be a carcinoma, a myeloma, a melanoma or a glioma. The peptide or polypeptide may be administered directly to said cancer cells, local to said cancer cells, regional to said cancer cells, or systemically. The method may further comprise administering to said subject a second cancer therapy selected from chemotherapy, radiotherapy, immunotherapy, hormonal therapy, or gene therapy.

In still yet a further embodiment, there is provided a method of treating a subject having a disease characterized by angiogenesis comprising contacting endothelial cells which express α5β3 or α5β3 integrin and are responsible for said angiogenesis, with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising at least or at most 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 or 32 contiguous amino acids from a synstatin sequence (or any range derivable therein), such as those defined by SEQ ID NOs:15, 17, 19, and 21. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28. The peptide or polypeptide may be 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length. The peptide or polypeptide may consist of or comprise SEQ ID NO:10. In other embodiments, the peptide may consist of or comprise SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28. The inhibiting may result in inhibition of cell adhesion, migration, cell metastasis, cell survival and/or cell proliferation.

In an additional embodiment, there is provided a method of inhibiting angiogenesis comprising contacting an endothelial cell expressing an α5β3 or an α5β3 integrin, comprising contacting said cells with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising SEQ ID NO:21 or SEQ ID NO:13. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28. The peptide or polypeptide may be 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length. The peptide or polypeptide may consist of or comprise SEQ ID NO:10. In other embodiments, the peptide may consist of or comprise SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28. The inhibiting may result in inhibition of cell adhesion, migration, cell metastasis, cell survival and/or cell proliferation.

In still yet a further embodiment, there is provided a method of treating a subject having a disease characterized by angiogenesis comprising contacting endothelial cells which express α5β3 or α5β3 integrin and are responsible for said angiogenesis, with a peptide or polypeptide segment consisting of between 5 and 100 amino acid residues or less residues and comprising at least or at most 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31 or 32 contiguous amino acids from a synstatin sequence (or any range derivable therein), such as those defined by SEQ ID NOs:15, 17, 19, and 21. In certain embodiments, the peptide does not have an amino acid sequence that consists of SEQ ID NO:28. The peptide or polypeptide may be 10, 15, 20, 25, 30, 35, 40, 45, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length. The peptide or polypeptide may consist of or comprise SEQ ID NO:10. In other embodiments, the peptide may consist of or comprise SEQ ID NO:1, SEQ ID NO:13, SEQ ID NO:21, SEQ ID NO:23, or SEQ ID NO:28. The inhibiting may result in inhibition of cell adhesion, migration, cell metastasis, cell survival and/or cell proliferation.

It is further contemplated that peptides or polypeptides of the invention may also include amino acid sequences from other proteins. These peptides and polypeptides would have an amino acid sequence from a non-syndecan-1 protein. Consequently, peptides or polypeptides of the invention may consist essentially of a syndecan-1 amino acid segment, such as those discussed herein, in which case they can have an amino acid segment from another protein. In particular embodiments, the other protein can be some kind of marker, targeting sequence, or stabilizer.

It is contemplated that any method or composition described herein can be implemented with respect to any other method or composition described herein.

The use of the word “a” or “an” when used in conjunction with the term “comprising” in the claims and/or the specification may mean “one,” but it is also consistent with the meaning of “one or more,” “at least one,” and “one or more than one.” The word “about” means plus or minus 5% of the stated number.

Other objects, features and advantages of the present invention will become apparent from the following detailed description. It should be understood, however, that the detailed description and the specific examples, while indicating specific embodiments of the invention, are given by way of illustration only, since various changes and modifications within the spirit and scope of the invention will become apparent to those skilled in the art from this detailed description.

BRIEF DESCRIPTION OF THE DRAWINGS

The following drawings form part of the present specification and are included to further demonstrate certain aspects of the present invention. The invention may be better understood by reference to one or more of these drawings in combination with the detailed.

FIGS. 1A-1C—Co-expression of Sdcl, α5β3 integrin and αβ3 integrin by endothelial cells during tumor-induced angiogenesis. (FIG. 1A) Wnt-1 induced mammary tumor. (FIG. 1B) β-catenin-induced mammary tumor. (FIG. 1C) Normal mouse artery. Endothelial cells are identified by staining with a rat monoclonal for PECAM. The integrin subunits are identified by staining with rabbit polyclonal antibodies to the β3 subunit (AB1932), β5 subunit (AB1926) and αC subunit (AB1930). Sdcl is visualized by an affinity purified rabbit polyclonal antibody directed against its extracellular domain. Rat IgG and Rabbit IgG controls are shown. The staining in the artery is shown as an overlay of the two antibodies used. Note that neither Sdcl nor the two integrins are expressed in the PECAM-positive endothelial cell layer, whereas they are in the tumors.
FIG. 2—Human aortic endothelial cells rely on αvβ3 and αvβ5 integrins for spreading on VN. Human aortic endothelial cells (HAECs) were suspended and replate at 10 μg/ml VN in the presence of integrin inhibitory antibodies mAb 13 (specifying β1-containing integrins; this will inhibit the αvβ3 integrin), LM609 (specific for the αvβ3 integrin) and P1F6 (specific for the αvβ5 integrin), or combinations of these mAbs. After 2 hr, the cells were fixed, stained with Alexa488-conjugated phalloidin to aid in visualization, and observed by fluorescence microscopy to document integrin-dependent spreading. Inhibition of spreading requires simultaneous inhibition of both αvβ3 and αvβ5 integrins.

FIG. 3—αvβ3 and αvβ5 integrin-mediated spreading of human aortic endothelial cells on VN is disrupted by recombinant Sdc1 ectodomain fusion protein. HAECs were plated on VN in the presence of no competitor, 10-10 M GST-mS1ED (recombinant mouse Sdc1 ectodomain expressed as a fusion protein with GST) or GST alone.

FIG. 4—Inhibition of HAEC spreading on VN by silencing of Sdc1. HAECs were transfected with a range of concentrations of siRNA specific for human Sdc1 (hS1), which achieves 80-88% silencing at 100-200 nM, as shown by flow cytometry using human Sdc1 mAb B-B4. The cells treated with 200 nM siRNA were also plated on VN for 2 hr and display a 60% reduction in cell spreading.

FIGS. 5A-5F—Inhibition of MDA-MB-231 human mammary carcinoma cell attachment and spreading on VN by synstatins 82-130. MDA-MB-231 human mammary carcinoma cells, which rely on the αvβ3 integrin for attachment and spreading on VN, were plated at 10 μg/ml VN for 2 hr in the absence of peptide (FIG. 5A) or in the presence of 0.1 (FIG. 5B), 0.3 (FIG. 5C) or 1 (FIG. 5D) synstatin 82-130. The cells were fixed and stained as in FIG. 2. As a control, cell adhesion and spreading on fibronectin, a ligand on which the cells use the α5β1 integrin and do not rely on the αvβ3 integrin; the control with no treatment (FIG. 5E) appears the same as when treated, i.e., synstatin 82-130 has no effect on attachment and spreading on this ligand (FIG. 5F).

FIGS. 6A-6H—Inhibition of B82L fibroblast and MHEC-1 cell attachment and spreading on VN by synstatins 82-130. B82L fibroblasts, which rely on the αvβ3 integrin for attachment to VN, and human dermal microvascular endothelial cells, which rely on both the αvβ3 and αvβ5 integrins for attachment to VN, were plated in the absence of peptide (FIGS. 6A, 6E) or in the presence of 0.1 (FIGS. 6B, 6F), 0.3 (FIGS. 6C, 6G) or (FIGS. 6D, 6H) synstatin 82-130 for 2 hr and processed as described in FIG. 2.

FIGS. 7A-7D—Synstatin 82-130 inhibits angiogenesis induced by FGF in vivo. A polyHEMA pellet containing 100 ng FGF was surgically inserted into the center of the mouse cornea. Test mice also received a 2 ml Alzet osmotic pump inserted subcutaneously on their backs, containing 100 μM synstatin 82-130. The mice were allowed to recover and were maintained for seven days before sacrifice. Fluorescent dextran was injected into the vascular system via retro-orbital injection just prior to sacrifice. (FIG. 7A) Mouse with FGF alone; (FIG. 7B) fluorescence image of the boxed area shown in FIG. 7A; (FIG. 7C) mouse with FGF-synstatin 82-130; (FIG. 7D) fluorescence image of boxed area shown in FIG. 7C. Note that the cornea is devoid of angiogenic vessels in the presence of systemic synstatin. Normal vessels are observed in the iris.

FIGS. 8A-8D—SSTN disrupts association of syndecan-1 with the αvβ3 and αvβ5 integrins. (FIG. 8A) Diagram of mouse syndecan-4 (mS4), human syndecan-1 (hS1) and mouse syndecan-1 (mS1) and mS1 deletion mutants showing which proteoglycans are able to activate the αvβ3 and αvβ5 integrins. (FIG. 8B) Flow cytometry of human aortic endothelial cells (HAEC), human dermal microvascular endothelial cells (HMEC-1) or mouse aortic endothelial cells (MAEC) using human or mouse-specific antibodies for syndecan-1, αvβ3, and αvβ5. The β3 subunit is detected by Western blot in mouse cells and is compared to B82L fibroblasts known to express this integrin; (FIG. 8C) Human syndecan-1 is immunoprecipitated from HMEC-1 cells in the presence or absence of 30 μM GST; 30 μM GST-sSTN (mouse syndecan-1 ectodomain), or 1 sSTN and detected on blots along with co-precipitating β3 or β5 integrin. (FIG. 8D) Human syndecan-1 is immunoprecipitated from MDA-MB-231 human mammary carcinoma cells expressing full-length mouse syndecan-1 (F1-mS1), a mouse mutant bearing deletion of amino acids 67-121 (mS1167-121), or vector alone (NEO) and blotted for the co-precipitation of the αvβ3 integrin by detection of the β3 subunit.

FIG. 8—I—Sequence of SSTN across species. The sequence of syndecan-1 in the vicinity of the αvβ3 and αvβ5 regulatory sites is shown for murine, hamster, rat and human. The numbering is for the murine sequence. The active site defined by deletion analysis is amino acids 88-121 in the mouse sequence. Note that human syndecan-1 has one additional amino acid N-terminal to the SSTN sequence; thus its numbering would be greater by one amino acid. A putative conserved sequence (cons) is shown (SEQ ID NO: 13) (72% homology).

FIGS. 9A and 9B—Sequence of SSTN across species. The sequence of syndecan-1 in the vicinity of the αvβ3 and αvβ5 regulatory sites is shown for murine, hamster, rat and human. The numbering is for the murine sequence. The active site defined by deletion analysis is amino acids 88-121 in the mouse sequence. Note that human syndecan-1 has one additional amino acid N-terminal to the SSTN sequence; thus its numbering would be greater by one amino acid. A putative conserved sequence (cons) is shown (SEQ ID NO: 13) (72% homology).

FIGS. 10A-10D—Dependence of HMEC cell attachment and spreading on integrin activation by Sdc1 and its inhibition by SSTN. (FIG. 10A) HMECs were plated for 2 hr either on Sdc1-specific antibody B-B4 to engage Sdc1 or on VN (10 μg/ml coating concentration) to engage the αvβ3 and αvβ5 integrins. Blocking antibodies LM609 (10 μg/ml, specific for αvβ3) and P1F6 (10 μg/ml, specific for αvβ5), SPTN (0.5 μM) or recombinant mouse Sdc1 ectodomain (mS1ED, 5 μM) were added. The ligand mimetic antibody WOW1 was used to detect activated αvβ3 integrin on cells plated on B-B4. (FIG. 10B) HMECs were treated with siRNA oligo specific for human Sdc1 for 48 hr prior to plating on VN. Sdc1 expression was quantified by flow cytometry using human Sdc1-specific mAb B-B4 or a control mouse IgG. (FIG. 10C-10D) The percentage of cell attaching or attaching and spreading was quantified for HMEC-1, HMEC and MHEC on VN for 2 hr in the presence of mS1ED or SSTN, or after siRNA silencing of Sdc1 expression in the presence of mAb LM609 to block αvβ3 integrin, P1F6 to block integrin, or both antibodies.

FIGS. 11A-11C—Syndecan-1 and the αvβ3 and αvβ5 integrins are co-expressed during aortic angiogenesis and in tumors. (FIG. 11A) Aortic explants were stained en face for expression of syndecan-1, αvβ3 and αvβ5 integrin (αv, β3 and β5) and PECAM. (FIG. 11B) Aortic segments explanted to collagen gels in the presence of 30 ng/ml fibroblast growth factor-2 (FGF-2) were stained after 7 days for expression of syndecan-1 and β3 or β5 integrin. (FIG. 11C) Frozen sections of spontaneous mouse mammary tumors from the wnt-1 or β-catenin overexpressing mice were stained for syndecan-1, PECAM, of integrin expression (αv, β3, β5).
FIG. 12—SSTN blocks aortic ring angiogenesis. Aortic segments were explanted to collagen gels for 7 days in the presence of 50 ng/ml vascular endothelial cell growth factor (VEGF), or 50 ng/ml FGF-2 in the presence of absence of mS1ED or SSTN. Total outgrowth in quantified as the total length of all microvessels.

FIG. 13—Inhibition of corneal angiogenesis by SSTN. PolyHEMA pellets (0.25 µL) containing 67 ng FGF-2 and sucrose were implanted into the avascular mouse cornea. Alzet pumps containing PBS, 2500 µM mS1ED or a range of SSTN concentrations (0-100 µM) were implanted subcutaneously on the back of the animals and angiogenesis for 7 days. Fluorescent dextran was injected suborbitally for 2 min prior to sacrifice for observation of the vascular system in dissected cornea (picture insets). Total angiogenesis is quantified as total length of vessels growing from the limbus vessels at the margin of the cornea.

FIG. 14—Activity of SSTN peptides. A diagram of SSTN82-130 used in our experiments is shown. The gray letters designate amino acids that are identical or highly conserved across species (mouse, human, rat, hamster). Shorter peptides have been tested using HMEC-1 endothelial cells for inhibition of α5β1 and α5β3 mediated cell attachment and spreading in comparison to SSTN82-130. SSTN82-130 (49-mer) is SEQ ID NO:22. SSTN88-122 (35-mer) is SEQ ID NO:23. SSTN95-130 (35-mer) is SEQ ID NO:24. SSTN88-117 (30-mer) is SEQ ID NO:25. SSTN88-106 (19-mer) is SEQ ID NO:26. SSTN80-103 (14-mer) is SEQ ID NO:27.

FIG. 15—SSTN-treated mice bearing CAG human myeloma tumors. 10² human CAG myeloma cells were injected subcutaneously into the backs of immunodeficient SCID mice. After 10 days, the mice were scanned to confirm establishment of luciferase-expressing tumors in all ten mice. Alzet pumps delivering 0.25 µl/hr of either PBS (control) or 100 µM SSTN were implanted and the tumors allowed to grow for an additional 28 days. Scanning of the tumors at this point (measured as photons/second/cm²/steradian) shows an 11-fold reduction in tumor size by SSTN treated mice were dissected and weighed after 28 days: control (238±92 g) and SSTN-treated (22±6 g) mice. Alzet pumps containing PBS, 2500 µM mS1ED or a range of SSTN concentrations (0-100 µM) were implanted subcutaneously on the back of the animals and angiogenesis for 7 days. Fluorescent dextran was injected suborbitally for 2 min prior to sacrifice for observation of the vascular system in dissected cornea (picture insets). Total angiogenesis is quantified as total length of vessels growing from the limbus vessels at the margin of the cornea.

The formation of new blood vessels, which occurs in development and disease, relies on inducing proliferation and migration of endothelial cells, and in controlling the survival or apoptosis of cells to sculpt the architecture of the new vessels (vascular pruning). The αvβ3 and αvβ5 integrins have important roles in all three of these steps. Surprisingly, work with αvβ3, αvβ5, or double αvβ3/αvβ5 knockout mice shows that angiogenesis in mice lacking one or both of these integrins is not blocked, and may be increased (Reynolds et al., 2002). One explanation for these results is that the main role of the integrins during normal angiogenesis is to act as a “brake” and to prune unwanted new vessels by activating cell death (apoptosis). Inhibitors that inactivate the integrin and thus disrupt cell migration that relies on these integrins have the additional effect of enhancing the apoptotic signal emanating from the integrins, leading to endothelial cell death. This death mechanism is lacking in mice in which the integrin gene is disrupted, and this may explain why apoptosis is not observed in these knockout mice.

A peptide representing the active site in the extracellular domain of Sdc1 (an inhibitory activity referred to as “synstatin”) competitively disrupts this positive regulation and blocks biological processes in which these two integrins participate, including angiogenesis. There are a number of anti-angiogenic compounds that have been described and many are in clinical trials. Some are generated in vivo, often by proteolysis of native matrix components, giving rise to angiostatin (O’Reilly et al., 1994), endostatin (O’Reilly et al., 1997), canstatin (Kamphaus et al., 2000), andumstatin (Maeshima et al., 2000). Tumstatin is of interest as it is derived from the α3 chain of collagen IV and the active site within tumstatin targets the αvβ3 integrin. In light of the inventors’ observations with regard to the activity of synstatin, the fact that Tumstatin...
The αβ3 and αβ5 Integrins

The αβ3 and αβ5 are closely related integrins that are upregulated during disease processes. The αβ3 integrin is a key regulator of adhesion and signaling in numerous biological processes, including tumor cell migration and metastasis, and angiogenesis. The activated form of this integrin participates in arrest of tumor cells in the blood stream (Plitch et al., 2002), enhancing their extravasation to target tissues, especially bone, where the activated integrin has further roles in tumor cell proliferation and survival (Brooks et al., 1994; Petriccione et al., 1999; Eliceiri et al., 2001). In endothelial cells forming new blood vessels, the active integrin is linked not only to adhesion-dependent processes but also to signaling in response to FGF-2 (Eliceiri et al., 1998; Hood et al., 2003).

Although αβ3 integrin expression in mammary epithelium is low, activated αβ3 is expressed on most, if not all, successful mammary carcinoma metastases (Liapis et al., 1996; Felding-Habermann et al., 2001). The inventors have reported previously that αβ3 integrin on MDA-MB-231 mammary carcinoma cells appears to be functionally linked to Sdc-1; the cells spread when adherent to an artificial ECM, enhancing their extravasation to target tissues, especially bone, where the activated integrin has further roles in tumor cell proliferation and survival (Brooks et al., 1994; Petriccione et al., 1999; Eliceiri et al., 2001). In endothelial cells forming new blood vessels, the active integrin is linked not only to adhesion-dependent processes but also to signaling in response to FGF-2 (Eliceiri et al., 1998; Hood et al., 2003).

The αβ3 integrin is expressed on a variety of tissues and cell types, including endothelia, epithelia and fibroblasts (Felding-Habermann and Cheresh, 1993; Pasqualini et al., 1993). It is closely related to the αβ5 integrin (56.1% identity and 83.5% homology between the two integrin β-subunits) but is distinguished from the αβ3 by divergent sites near its ligand-binding domain and within the C-terminus of its cytoplasmic tail (McLean et al., 1990). It has a role in matrix adhesion to VN, FN, SPARC and bone sialoprotein (Plow et al., 2000) and is implicated in the invasion of gliomas and metastatic carcinoma cells (Brooks et al., 1997; Jones et al., 1997; Tonn et al., 1998), the latter especially to bone (De et al., 2003). A second major role is in endocytosis, including endocytosis of VN (Memmo and McKeown-Longo, 1998; Panetti et al., 1995), the engulfment of apoptotic cells by phagocytes (Albert et al., 2000), and participation in the internalization of shed outer rod segments in the retinal pigmented epithelium (Finnemann, 2003a; Finnemann, 2003b; Hull et al., 2003). A third major role is in growth factor-induced angiogenesis, where cooperative signaling by the αβ3 integrin and growth factors regulates endothelial cell proliferation and survival. Angiogenesis promoted by VEGF and TGFβ collaborate with the αβ3 integrin, whereas FGF-2 and tumor necrosis factor-α collaborate with the αβ3 integrin (Eliceiri and Cheresh, 1999; Friedlander et al., 1995).

The vertebrate syndecans are a family of four transmembrane HS PGs. Endowed by their heparan sulfate (HS) chains, syndecans bind a variety of ECM ligands, including fibronectin (FN), laminin (LN), tenascin, thrombospondin (TSP), vitronectin (VN) and the fibrillar collagens (COL) (Bernfeld et al., 1999). While the syndecan HS chains are essential for matrix binding, less is known about the role of syndecan core proteins in cell adhesion and signaling, although the core protein can affect ligand binding interactions, as well as occupancy induced signaling (Rapraeger and Ott, 1998; Rapraeger, 2000).

The syndecans display a high degree of conservation within their core proteins both across species and across family members. Like the integrins, the syndecans lack intrinsic signaling activity. Their short cytoplasmic tails (ca. 30 aa) consist of three regions, two of which are conserved amongst the four syndecans (C1 and C2) and which flank an intervening variable (V) region. Proteins known to interact with these conserved domains are believed to link syndecan ligand binding interactions to the transduction of intracellular signals (Couchman et al., 2001). Each family member is uniquely defined by its ectodomains and the V-regions of its cytoplasmic tail. Divergence within these regions is believed to confer separate and distinct functions to each individual family member. Distinct roles for the V-regions of Sdc-2 and Sdc-4 in matrix assembly and focal adhesion formation respectively have been described (Klass et al., 2000; Woods and Couchman, 2001); however, specific functions for the syndecan ectodomains are almost wholly unknown with the noted exception of Sdc-1 and Sdc-4 which contain binding sites for as yet unidentified cell surface receptor(s) (McFall and Rapraeger, 1997; McFall and Rapraeger, 1998).

B. Syndecan Function in Cell Adhesion and Spreading

Current evidence suggests that the syndecan core proteins participate in adhesion-mediated signaling in collaboration with co-receptors at the cell surface. One example is Sdc-4
in focal adhesion and stress fiber formation, which requires both Sdc-4 and integrin engagement whereas neither is sufficient alone (Woods et al., 1986; Izzard et al., 1986; Streeter and Rees, 1987; Singer et al., 1987). The requirement for Sdc-4 ligation can be overcome by treatment with phosphatases (Woods and Coughman, 1994) or lysophosphatidic acid (LPA) (Saoncella et al., 1999) implicating PKC and RhoA in Sdc-4 signaling. While the mechanism by which Sdc-4 contributes to RhoA activation is not clear, it is known that Sdc-4 interacts directly with PKCα as well as phosphatidyl inositol 4,5 bisphosphate (PIP2) via its cytoplasmic tail and these interactions potentiate PKCα activity (Oh et al., 1997a; Oh et al., 1997b; Oh et al., 1998; Baciu and Goetinck, 1995).

While the mechanism by which Sdc-1 signals is not clear, there is ample evidence implicating a signaling role for this receptor as well. Ectopic expression of Sdc-1 in Schwann cells enhances cell spreading and promotes the formation of focal adhesions (Hansen et al., 1994) and activin stress fibers (Carey et al., 1994a); similar morphological changes occur when Sdc-1 is co-clustered with antibodies (Carey et al., 1994b). This response requires the cytoplasmic domain, since clustering of a truncated core protein did not induce reorganization of the cytoskeleton. Expression of Sdc-1 in human ARIH-77 leukemia cells or hepatocellular carcinoma cells inhibits invasion of cells into COL matrices (Liu et al., 1998; Ohtake et al., 1999). ARIH-77 cells expressing a chimera comprised of the Sdc-1 ectodomain fused to the glycosyl-phosphatidylinositol (GPI) tail of glycpcian-1 also fail to invade a COL matrix demonstrating that Sdc-1’s anti-invasive activity resides in its extracellular domain. In similar studies, Raji human lymphoblastoid cells transfected with mouse Sdc-1 (Raji-S1) spread on TSP, FN and antibodies directed against the Sdc-1 ectodomain (Lebakken and Rapraeger, 1996). This spreading is unaffected by truncation of the cytoplasmic domain, indicating that the Sdc-1 core protein interacts with and cooperatively signals through an associated transmembrane signaling partner. Analagous features have also been observed for Sdc-2 (Granes et al., 1999) and Sdc-4 (Yamashita et al., 1999).

Potential syndecan signaling partners include cell surface integrins. Iba et al. (2000) demonstrated that mesenchymal cells when seeded on an HS-specific ligand, the cysteine rich domain of a disintegrin and metalloprotease, ADAM-12/ Meltrin α (αADAM12-ctns), will spread in a manner that requires cooperative signaling of both syndecans and β1 integrins. These results imply that syndecan(s) can trigger signaling cascades required for cell spreading either by exposing a cystic binding site for β1 integrins, as has been proposed for FN (Khan et al., 1988), or by modulating the activation state of β1 integrins. Interestingly, colon carcinoma cells attach but fail to spread on αADAM12-ctns. However, exogenous stimulation of β1 integrins with Mn2+ or β1 integrin function activating antibody, mAb 12G10, induced cell spreading, suggesting a mechanism whereby the syndecan activates β1 integrins is blocked in transformed cells.

C. Angiogenesis

The formation of new blood vessels, called angiogenesis, which occurs in normal development as well as in disease states, relies on inducing proliferation and migration of endothelial cells, and in controlling the survival or apoptosis of the cells to control the architecture of the new vessels (vascular pruning). The ανβ3 integrin has important roles in all three of these steps.

FGF and VEGF, two growth factors that are often released by tumors, cause endothelial cells to undergo angiogenesis. Blood vessels in the vicinity of the tumor respond to VEGF by becoming leaky (thus the alternate name “vascular permeability factor”) allowing fibronectin, vitronectin and fibrinogen in the blood to infiltrate the surrounding matrix. These matrix ligands are critical adhesion and activation ligands for the ανβ3 and ανβ5 integrins, which have roles in the chemotactic migration of the endothelial cells and in the survival of the cells during vessel pruning. A second response to the growth factors, particularly FGF, is the activation of a neovessel development program that relies on Hox master genes (Bourdreau et al., 1997; Myers et al., 2000; 2002). HoxD3 is initially expressed and controls a family of genes that are necessary for the initial migration process, including upregulation of the ανβ3 integrin, MMPs and uPAR (Bourdreau et al., 1997). Expression of HoxD3 is followed by HoxB3 that regulates the morphogenesis leading to formation of small vessels (Myers et al., 2000), and finally by the HoxDI0 gene, which restores the mature phenotype of the cells (Myers et al., 2002); it is HoxD10 that is expressed in resting, stable blood vessels in vivo.

The ανβ3 integrin is important not only during endothelial cell migration, but is an important player in the survival of the endothelial cells. Although endothelial cells in mature vessels are not readily susceptible to apoptosis, angiogenic cells that are induced by growth factors rely upon the continued presence of these factors for survival. This is shown experimentally by inducing angiogenesis with VEGF and causing apoptosis by its withdrawal, or in vivo when the developing ovarian follicle induces angiogenesis by release of VEGF and the newly formed bloods vessels regress upon ovulation as the source of VEGF is lost. Endothelial cells responding to VEGF have been shown to be dependent on signaling from the ανβ3 integrin in order to block this apoptotic process (Brooks et al., 1994; Friedlander et al., 1995). Thus, inhibiting the integrin using anti-integrin antibodies will induce apoptosis of the endothelial cells responding to VEGF. Similarly, endothelial cells responding to fibroblast growth factor (FGF) are susceptible to apoptosis unless there is coordinate signaling from the ανβ5 integrin.

There are a number of anti-angiogenic compounds that have been described and many are in clinical trials. Some are generated in vivo, potentially the proteolysis of native matrix components, giving rise to angiostatin (O’Reilly et al., 1994), endostatin (O’Reilly et al., 1997), canstatin (Kamphaus et al., 2000), arresten (Colorado et al., 2000) and tumstatin (Maeshima et al., 2000). Tumstatin is of interest as it is derived from the α3 chain of Collagen IV and active site within tumstatin is a peptide binding site that targets the ανβ3 integrin, although it appears distinct from the RDG binding site of the integrin. Tumstatin inhibits the proliferation of endothelial cells and is a highly effective inhibitor in angiogenesis assays. As this invention describes the regulation of the ανβ3 integrin by Sdc-1 in mammary carcinoma cells and in endothelial cells, and this dependence can be blocked by soluble SlED, it is hypothesized that this inhibitor would be an effective inhibitor of angiogenesis as well. Perhaps more intriguing is its activity only against the endothelial cells that express Sdc-1. Although there is not much information available, the information to date indicates that resting endothelial cells lining adult blood vessels do not express Sdc-1. In contrast, expression of Sdc-1 is turned on when the cells are activated to undergo angiogenesis, such as occurs normally in wounding, or occurs in abnormal conditions such as diabetic retinopathy, restenosis following blood catheter injury to blood vessels, or tumor angiogenesis. Thus, it is intriguing that targeting the Sdc-1
regulation of the αβ3 integrin can provide not only an additional opportunity for drug discovery, but the drug may be most efficacious during angiogenesis itself.

There has not been a concerted examination of Sdc-1 expression in vascular endothelium. Most reports suggest that it is expressed poorly or not at all on resting, mature vascular endothelium that lines blood vessels. However, there are reports that suggest it is expressed on activated endothelial cells participating in angiogenesis in the wounded skin (Ellenius et al., 1991; Gallo et al., 1996). Sdc-1 is not expressed in endothelial cells lining the rabbit aorta, but expression is upregulated following balloon catheter injury and persists for up to 12 weeks following injury. There is a report that Sdc-1 is upregulated in a subset of vessels during tumor angiogenesis (Gotte et al., 2002). These studies strongly suggest that Sdc-1 becomes expressed in the response to injury or growth factors. Cultured cells, such as human aortic and human umbilical vein endothelial cells show expression at both the protein and mRNA level, although expression in human umbilical vein endothelial cells is low (Mertens et al., 1992). However, the expression patterns described may be dependent on the growth factors and supplements, such as brain extract, added to the culture medium.

D. Syndecan-1

Syndecan-1 is highly expressed at the basolateral surface of epithelial cells where it is thought to interact with the actin cytoskeleton and to modulate cell adhesion and growth factor signaling (Bernfield et al., 1999; Rapraeger et al., 1986; Kim et al., 1994; Sanderson and Bernfield, 1988). In experimental studies of malignant transformation, Sdc-1 expression is associated with the maintenance of epithelial morphology, anchorage-dependent growth and inhibition of invasiveness. Alterations in syndecan expression during development (Sun et al., 1998) and in transformed epithelial (Inki and Jalkanen, 1996; Bayer-Garnier et al., 2001) are associated with an epithelial-to-mesenchymal transformation with attendant alterations in cell morphology, motility, growth and differentiation. Transfection of epithelial cells with anti-sense mRNA for Sdc-1 or downregulation of Sdc-1 expression by androgen-induced transformation results in an epithelial to mesenchymal transformation and increased invasion (Leppa et al., 1992; Kato et al., 1995; Leppa et al., 1991). The loss of E-cadherin under these circumstances has long suggested a coordinate regulation of Sdc-1 and E-cadherin expression (Sun et al., 1998; Leppa et al., 1996). These studies, as well as others, indicate that there appears to be a threshold requirement for syndecan expression to elicit its biological activity. Syndecan-1 is downregulated in a number of epithelial cancers and in pre-malignant lesions of the oral mucosa (Soutkka et al., 2000) and uterine cervix (Inki et al., 1994; Rintala et al., 1999; Nakanishi et al., 1999), and its loss may be an early genetic event contributing to tumor progression (Sanderson, 2001; Numda et al., 2002; Hirabayashi et al., 1998). Loss of Sdc-1 correlates with a reduced survival in squamous cell carcinoma of the head, neck and lung (Anttonen et al., 1999; Inki et al., 1994; Nakaerts et al., 1997), laryngeal cancer (Pulkkinen et al., 1997; Klatka, 2002), malignant mesothelioma (Kumar-Singh et al., 1998) and multiple myeloma (Sanderson and Borset, 2002) and a high metastatic potential in hepatocellular and colorectal carcinomas (Matsumoto et al., 1997; Fujiya et al., 2001; Levy et al., 1997; Levy et al., 1996). Downregulation of Sdc-2 and -4 expression has also been observed in certain human carcinomas (Nakaerts et al., 1997; Park et al., 2002; Mundhenke et al., 2002; Crescimanno et al., 1999), but the functional consequences of these alterations in expression are less clear.

In contrast to the general notion that the syndecan may be an inhibitor of carcinogenesis, Sdc-1 also demonstrates tumor promoter function. Syndecan-1 supplements Wnt-1-induced tumorigenesis of the mouse mammary gland (Alexander et al., 2000) and promotes the formation of metastases in mouse lung squamous carcinoma cells (Hirabayashi et al., 1998). Enhanced Sdc-1 expression has also been observed in pancreatic (Conejo et al., 2000), gastric (Wiksten et al., 2001) and breast (Burbach et al., 2003; Stanley et al., 1999; Barbareschi et al., 2003) carcinomas and this overexpression correlates with increased tumor aggressiveness and poor clinical prognosis. This duality in the role of Sdc-1 in tumorigenesis may reflect tissue and/or tumor stage-specific function, or reflect the multiple functions of this PG.

Sanderson was the first to demonstrate a role for Sdc-1 in tumor cell migration by examining the invasion of myeloma cells into collagen gels (Liu et al., 1998). Ectopic expression of Sdc-1 in syndecan-deficient myeloma cells had the striking effect of curtailing invasion, whereas the expression of other cell surface heparan sulfate PGs (e.g., glypican) was without effect. Using chimeras derived from these two proteins, Sanderson showed that the activity of the syndecan is preserved when its ectodomain alone is expressed as a glycosyl-phosphatidylinositol (GPI)-linked protein at the cell surface. Although clearly responsible for binding the collagen matrix via its attached heparan sulfate chains, the anti-invasive activity of the syndecan requires yet an additional interaction that traces to a site in the extracellular domain of the core protein itself. The mechanism by which the ectodomain site influences the invasion of the myeloma cells is unknown, but its interaction with other cell surface receptors in a "co-receptor" role is one possibility. More recently, ectopic expression of Sdc-1 has also been shown to curtail the invasion of hepatocellular carcinoma cells into a collagen matrix (Ohtake et al., 1999).

E. Proteins and Peptides

Syndecan-1 peptides and polypeptides of the present invention will generally comprise molecules of 5 to about 240 residues in length, and may have the sequence of SEQ ID NO:1 or SEQ ID NO:4 or SEQ ID NO:8 or SEQ ID NO:9 or SEQ ID NO:10 or SEQ ID NO:13 or SEQ ID NO:21 or SEQ ID NO:23 or SEQ ID NO:28. A particular length may be 234 residues, 34 residues, 32 residues, less than 30 residues, less than 25 residues, less than 20 residues, less than 15 residues, or less than 14 residues, including 5, 6, 7, 8, 9, 10, 11, 12, or 13 residues. In other embodiments, the peptides or proteins may be from SEQ ID NOS:2, 4, 8, 9, 13, 21, 23, or 28 and may thus comprise 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 49, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 210, 220, 230, or 240 consecutive residues of that sequence. Alternatively, the peptides may have 90%, 95%, or more identity with the SEQ ID NOS identified herein. It is further contemplated that any embodiment involving a mouse sequence discussed herein may be implemented with the corresponding human sequence. Such human peptides and nucleic acids encoding such peptides are specifically contemplated as part of the invention.

The peptides or proteins may be generated synthetically or by recombinant techniques, and are purified according to known methods, such as precipitation (e.g., ammonium sulfate), HPLC, ion exchange chromatography, affinity chro-
matography (including immunoaffinity chromatography) or various size separations (sedimentation, gel electrophoresis, gel filtration).

Accordingly, sequences that have between about 70% and about 80%, between about 81% and about 90%, between about 91% and 95%, or about 96%, about 97%, 98% or about 99% of amino acids that are identical or functionally equivalent to the amino acids of SEQ ID Nos: 2, 4, 8, 9 or 10, will be sequences that are “essentially as set forth in SEQ ID Nos: 2, 4, 8, 9 or 10.” Peptides and polypeptides of the invention may be as essentially as set forth in SEQ ID Nos: 2, 4, 8, 9 or 10.

1. Substitutional Variants

It also is contemplated in the present invention that variants or analogs of syndecan-1 peptides or proteins may also inhibit tumor growth. Polypeptide sequence variants of syndecan-1, primarily making conservative amino acid substitutions to SEQ ID Nos: 2, 4, 8, 9 or 10, may provide improved compositions. Substitutional variants typically contain the exchange of one amino acid for another at one or more sites within the protein, and may be designed to modulate one or more properties of the polypeptide, such as stability against proteolytic cleavage, without the loss of other functions or properties. Substitutions of this kind preferably are conservative, that is, one amino acid is replaced with one of similar shape and charge. Conservative substitutions are well known in the art and include, for example, the changes of: alanine to serine; arginine to lysine; asparagine to glutamine or histidine; aspartate to glutamate; cysteine to serine; glutamine to asparagine; glutamate to aspartate; glycine to proline; histidine to asparagine or glutamine; isoleucine to leucine or valine; leucine to valine or isoleucine; lysine to arginine; methionine to leucine or isoleucine; phenylalanine to tyrosine, leucine or methionine; serine to threonine; threonine to serine; tryptophan to tyrosine; tyrosine to tryptophan or phenylalanine; and valine to isoleucine or leucine.

The following is a discussion based upon changing of the amino acids of a peptide or protein to create an equivalent, or even an improved, second-generation molecule. For example, certain amino acids may be substituted for other amino acids in a protein structure without appreciable loss of interactive binding capacity with structures such as, for example, antigen-binding regions of antibodies or binding sites on substrate molecules. Since it is the interactive capacity and nature of a peptide that defines that peptide’s biological functional activity, certain amino acid substitutions can be made in a protein sequence, and its underlying DNA coding sequence, and nevertheless obtain a peptide with like properties. It is thus contemplated by the inventors that various changes may be made in syndecan-1 amino acid sequences and in the DNA sequences coding the peptide without appreciable loss of their biological utility or activity, as discussed below.

In making such changes, the hydrophobic index of amino acids may be considered. The importance of the hydrophobic amino acid index in conferring interactive biologic function on a protein is generally understood in the art (Kyte and Doolittle, 1982). It is accepted that the relative hydrophobic character of the amino acid contributes to the secondary structure of the resultant peptide, which in turn defines the interaction of the peptide with other molecules.

Each amino acid has been assigned a hydropathic index (being the basis of their hydrophobicity and charge characteristics (Kyte and Dooitle, 1982), these are: isoleucine (+4.5); valine (+4.2); leucine (+3.8); phenylalanine (+2.8); cysteine/cystine (+2.5); methionine (+1.9); alanine (+1.8); glycine (-0.4); threonine (-0.7); serine (-0.8); tryptophan (-0.9); tyrosine (-1.3); proline (-1.6); histidine (-3.2); glutamate (-3.5); glutamine (-3.5); aspartate (-3.5); asparagine (-3.5); lysine (-3.9); and arginine (-4.5).

It is known in the art that certain amino acids may be substituted by other amino acids having a similar hydrophobic index or score and still result in a peptide with similar biological activity, i.e., still obtain a biological functionally equivalent protein. In making such changes, the substitution of amino acids whose hydrophobic index are within ±2 is preferred, those which are within ±1 are particularly preferred, and those within ±0.5 are even more particularly preferred.

It is also understood in the art that the substitution of like amino acids can be made effectively on the basis of hydrophilicity. U.S. Pat. No. 4,554,101, incorporated herein by reference, states that the greatest local average hydrophilicity of a protein, as governed by the hydrophilicity of its adjacent amino acids, correlates with a biological property of the protein. As detailed in U.S. Pat. No. 4,554,101, the following hydrophilicity values have been assigned to amino acid residues: arginine (+3.0); lysine (+3.0); aspartate (+3.0±1); glutamate (+3.0±1); serine (+0.3); asparagine (+0.2); glutamine (+0.2); glycine (0); threonine (-0.4); proline (-0.5±1); alanine (-0.5); histidine (-0.5); cysteine (-1.0); methionine (-1.3); valine (-1.5); leucine (-1.8); isoleucine (-1.8); tyrosine (-2.3); phenylalanine (-2.5); tryptophan (-3.4).

It is understood that an amino acid can be substituted for another having a similar hydrophilicity value and still obtain a biologically equivalent and immunologically equivalent protein. In such changes, the substitution of amino acids whose hydrophilicity values are within ±2 is preferred, those that are within ±1 are particularly preferred, and those within ±0.5 are even more particularly preferred.

As outlined above, amino acid substitutions are generally based on the relative similarity of the amino acid side-chain substituents, for example, their hydrophobicity, hydrophilicity, charge, size, and the like. Exemplary substitutions that take various of the foregoing characteristics into consideration are well known to those of skill in the art and include: arginine and lysine; glutamate and aspartate; serine and threonine; glutamine and asparagine; and valine, leucine and isoleucine.

Another embodiment for the preparation of polypeptides according to the invention is the use of peptide mimetics. Mimetics are peptide containing molecules that mimic elements of protein secondary structure (Johnson et al, 1993). The underlying rationale behind the use of peptide mimetics is that the peptide backbone of proteins exists chiefly to orient amino acid side chains in such a way as to facilitate molecular interactions, such as those of antibody and antigen. A peptide mimetic is expected to permit molecular interactions similar to the natural molecule. These principles may be used, in conjunction with the principles outline above, to engineer second generation molecules having many of the natural properties of syndecan-1, but with altered and even improved characteristics.

ii. Altered Amino Acids

The present invention may employ peptides that comprise modified, non-natural and/or unusual amino acids. A table of exemplary, but not limiting, modified, non-natural and/or unusual amino acids is provided herein below. Chemical synthesis may be employed to incorporate such amino acids into the peptides of interest.

iii. Mimetics

In addition to the variants discussed above, the present inventors also contemplate that structurally similar compounds may be formulated to mimic the key portions of peptide or polypeptides of the present invention. Such compounds, which may be termed peptidomimetics, may be used in the same manner as the peptides of the invention and, hence, also are functional equivalents.

Certain mimetics that mimic elements of protein secondary and tertiary structure are described in Johnson et al. (1993). The underlying rationale behind the use of peptide mimetics is that the backbone of proteins exists chiefly to orient amino acid side chains in such a way as to facilitate molecular interactions, such as those of antibody and/or antigen. A peptide mimetic is thus designed to permit molecular interactions similar to the natural molecule.

Some successful applications of the peptide mimetic concept have focused on mimetics of \( \beta \)-turns within proteins, which are known to be highly antigenic. Likely \( \beta \)-turn structures within a polypeptide can be predicted by computer-based algorithms, as discussed herein. Once the component amino acids of the turn are determined, mimetics can be constructed to achieve a similar spatial orientation of the essential elements of the amino acid side chains.

Other approaches have focused on the use of small, multidisulfide-containing proteins as attractive structural templates for producing biologically active conformations that mimic the binding sites of large proteins (Vita et al., 1998). A structural motif that appears to be evolutionarily preserved in certain toxins is small (30-40 amino acids), stable, and high permissive for mutation. This motif is composed of a beta sheet and an alpha helix bridged in the interior core by three disulfides. Beta II turns have been mimicked successfully using cyclic L-pentapeptides and those with D-amino acids (Weisshoff et al., 1999). Also, Johannesson et al. (1999) report on bicyclic tripeptides with reverse \( \beta \)-turn inducing properties.

Methods for generating specific structures have been disclosed in the art. For example, alpha-helix mimetics are disclosed in U.S. Pat. Nos. 5,446,128; 5,710,245; 5,840,833; and 5,859,184. These structures, which render the peptide or protein more thermally stable, also increase resistance to proteolytic degradation. Six, seven, eleven, twelve, thirteen and fourteen membered ring structures are disclosed.

Methods for generating conformationally restricted beta turns and beta bulges are described, for example, in U.S. Pat. Nos. 5,440,013; 5,618,914; and 5,670,155. Beta-turns permit changed side substituents without having changes in corresponding backbone conformation, and have appropriate termini for incorporation into peptides by standard synthesis procedures. Other types of mimetic turns include reverse and gamma turns. Reverse turn mimetics are disclosed in U.S. Pat. Nos. 5,745,085 and 5,929,237, and gamma turn mimetics are described in U.S. Pat. Nos. 5,672,681 and 5,674,976.

iv. D Amino Acids

In another form, the present invention contemplates use of variants that comprise various portions of an syndecan-1 peptide or protein in reverse order of SEQ ID Nos. 2, 4, 8, 9 or 10, using D amino acids, stereoisomers of natural amino acids which are in the L-form.

v. Peptide Synthesis

Syndecan-1 and related peptides may be generated synthetically for use in various embodiments of the present invention. Because of their relatively small size, the peptides of the invention can be synthesized in solution or on a solid support in accordance with conventional techniques. Various automatic synthesizers are commercially available and can be used in accordance with known protocols. See, for example, Stewart and Young (1984); Tam et al. (1983); Merrifield (1986); Barany and Merrifield (1979), each incorporated herein by reference. Short peptide sequences, or libraries of overlapping peptides, usually from about 5 up to about 34 to 40 amino acids, which correspond to the selected regions described herein, can be readily synthesized and then screened in screening assays designed to identify reactive peptides. Alternatively, recombinant DNA technology may be employed wherein a nucleotide sequence which encodes a peptide of the invention is inserted into an expression vector, transformed or transfected into an appropriate host cell and cultivated under conditions suitable for expression.

It may be desirable to purify syndecan-1 variants, peptide-mimics or analogs thereof. Protein purification techniques are well known to those of skill in the art. These techniques involve, at one level, the crude fractionation of the cellular milieu to polypeptide and non-polypeptide fractions. Having separated the polypeptide from other proteins, the polypeptide of interest may be further purified using chromatographic and electrophoretic techniques to achieve partial or complete purification (or purification to homogeneity). Analytical methods particularly suited to the preparation of a pure peptide are ion-exchange chromatography, exclusion chromatography; polyacrylamide gel electrophoresis; isoelectric focusing. A particularly efficient method of purifying peptides is fast protein liquid chromatography or even HPLC.

Certain aspects of the present invention concern the purification, and in particular embodiments, the substantial purification, of an encoded protein or peptide. The term "purified protein or peptide" as used herein, is intended to refer to a composition, isolatable from other components, wherein the protein or peptide is purified to any degree relative to its naturally-obtainable state. A purified protein or peptide therefore also refers to a protein or peptide, free from the environment in which it may naturally occur.

Generally, "purified" will refer to a protein or peptide composition that has been subjected to fractionation to remove various other components, and which composition substantially retains its expressed biological activity. Where the term "substantially purified" is used, this designation will refer to a composition in which the protein or peptide forms the major component of the composition, such as...
constituting about 50%, about 60%, about 70%, about 80%, about 90%, about 95% or more of the proteins in the composition.

Various methods for quantifying the degree of purification of the protein or peptide will be known to those of skill in the art in light of the present disclosure. These include, for example, determining the specific activity of an active fraction, or assessing the amount of polypeptides within a fraction by SDS/PAGE analysis. A preferred method for assessing the purity of a fraction is to calculate the specific activity of the fraction, to compare it to the specific activity of the initial extract, and to thus calculate the degree of purity, herein assessed by a “fold purification number.” The actual units used to represent the amount of activity will, of course, be dependent upon the particular assay technique chosen to follow the purification and whether or not the expressed protein or peptide exhibits a detectable activity. Various techniques suitable for use in protein purification will be well known to those of skill in the art. These include, for example, precipitation with ammonium sulphate, PEG, antibodies and the like or by heat denaturation, followed by centrifugation; chromatography steps such as ion exchange, gel filtration, reverse phase, hydroxylapatite and affinity chromatography; isoelectric focusing; gel electrophoresis; and combinations of such and other techniques. As is generally known in the art, it is believed that the order of conducting the various purification steps may be changed, or that certain steps may be omitted, and still result in a suitable method for the preparation of a substantially purified protein or peptide.

There is no general requirement that the protein or peptide always be provided in their most purified state. Indeed, it is contemplated that less substantially purified products will have utility in certain embodiments. Partial purification may be accomplished by using fewer purification steps in combination, or by utilizing different forms of the same general purification scheme. For example, it is appreciated that a cation-exchange column chromatography performed utilizing an HPLC apparatus will generally result in a greater “fold” purification than the same technique utilizing a low pressure chromatography system. Methods exhibiting a lower degree of relative purification may have advantages in total recovery of protein product, or in maintaining the activity of an expressed protein.

It is known that the migration of a polypeptide can vary, sometimes significantly, with different conditions of SDS/PAGE (Capaldi et al., 1977). It will therefore be appreciated that under differing electrophoresis conditions, the apparent molecular weights of purified or partially purified expression products may vary.

High Performance Liquid Chromatography (HPLC) is characterized by a very rapid separation with extraordinary resolution of peaks. This is achieved by the use of very fine particles and high pressure to maintain an adequate flow rate. Separation can be accomplished in a matter of minutes, or at most an hour. Moreover, only a very small volume of the sample is needed because the particles are so small and close-packed that the void volume is a very small fraction of the bed volume. Also, the concentration of the sample need not be very great because the bands are so narrow that there is very little dilution of the sample.

Gel chromatography, or molecular sieve chromatography, is a special type of partition chromatography that is based on molecular size. The theory behind gel chromatography is that the column, which is prepared with tiny particles of an inert substance that contain small pores, separates larger molecules from smaller molecules as they pass through or around the pores, depending on their size. As long as the material of which the particles are made does not adsorb the molecules, the sole factor determining rate of flow is the size. Hence, molecules are eluted from the column in decreasing size, so long as the shape is relatively constant. Gel chromatography is unsurpassed for separating molecules of different size because separation is independent of all other factors such as pH, ionic strength, temperature, etc. There also is virtually no adsorption, less zone spreading and the elution volume is related in a simple matter to molecular weight.

Affinity Chromatography is a chromatographic procedure that relies on the specific affinity between a substance to be isolated and a molecule that it can specifically bind to. This is a receptor-ligand type interaction. The column material is synthesized by covalently coupling one of the binding partners to an insoluble matrix. The column material is then able to specifically adsorb the substance from the solution. Elution occurs by changing the conditions to those in which binding will not occur (alter pH, ionic strength, temperature, etc.).

The matrix should be a substance that itself does not adsorb molecules to any significant extent and that has a broad range of chemical, physical and thermal stability. The ligand should be coupled in such a way as to not affect its binding properties. The ligand should also provide relatively tight binding. And it should be possible to elute the substance without destroying the sample or the ligand. One of the most common forms of affinity chromatography is immunoaffinity chromatography. The generation of antibodies that would be suitable for use in accord with the present invention is discussed below.

IV. Anti-Idiotypic Antibodies

The present invention also provide antibodies that mimic the syndecan-1 peptides and proteins described herein. These antibodies are created by first preparing an antibody against a syndecan-1 peptide or protein and then preparing a second antibody, called an anti-idiotypic antibody, against the idiotype of the first antibody. As a mirror image of a mirror image, the binding site of anti-idiotype would be expected to be an analog of the original antigen. As used herein, the term “antibody” is intended to refer broadly to any immunologic binding agent such as IgG, IgM, IgA, IgD and IgE. Generally, IgG and/or IgM are preferred because they are the most common antibodies in the physiological situation and because they are most easily made in a laboratory setting.

The term “antibody” is used to refer to any antibody-like molecule that has an antigen-binding region which includes antibody fragments such as Fab, Fab, F(ab')2, single domain antibodies (DABs), Fv, scFv (single chain Fv), and the like. The techniques for preparing and using various antibodies and antibody-based constructs and fragments are well known in the art (see, e.g., Harlow et al., 1988; and U.S. Pat. No. 4,196,265 each incorporated herein by reference).

V. Nucleic Acid Sequences Encoding Syndecan Peptides and Proteins

The present invention concerns nucleic acid segments, isolatable from cells, that are free from total genomic DNA and that are capable of expressing all or part of a protein or polypeptide such as syndecan-1 or the syndecan-1 peptide or protein of SEQ ID NOs.2, 4, 8, 9, 10, 21, 23, or 28. The
nucleic acid may encode a peptide or polypeptide containing all or part of the syndecan-1 amino acid sequence.

As used herein, the term “nucleic acid segment” refers to a DNA molecule that has been isolated free of total genomic DNA of a particular species. Therefore, a nucleic acid segment encoding a syndecan-1 refers to a nucleic acid segment that contains wild-type, polymorphic, or mutant polypeptide-coding sequences that are isolated away from, or purified free from, total mammalian or human genomic DNA. Included within the term “nucleic acid segment” are a polypeptide(s), nucleic acid segments smaller than a polypeptide, and recombinant vectors, including, for example, plasmids, cosmids, plasmid, virus, and the like.

The term “cDNA” is intended to refer to DNA prepared using messenger RNA (mRNA) as template. The advantage of using a cDNA, as opposed to genomic DNA or DNA polymerized from a genomic, non- or partially-processed RNA template, is that the cDNA primarily contains coding sequences of the corresponding protein. There may be times when the full or partial genomic sequence is preferred, such as where the non-coding regions are required for optimal expression or where non-coding regions such as introns are to be targeted in an antisense strategy.

A nucleic acid segment encoding all or part of a native or modified polypeptide may contain a contiguous nucleic acid sequence encoding all or a portion of such a polypeptide of the following lengths: about 10, about 20, about 30, about 40, about 50, about 60, about 70, about 80, about 90, or about 100, about 110, about 120, about 130, about 140, about 150, about 160, about 170, about 180, about 190, about 200, about 210, about 220, about 230, about 240, about 250 or about 260 nucleotides, nucleosides, or base pairs. Specifically contemplated are a segment encoding SEQ ID NO:2, a segment encoding the 34 residue peptide of SEQ ID NO:2, a segment encoding residues 18-251 residues of SEQ ID NO:2, a segment encoding the 34 residue peptide of SEQ ID NO:2, a segment encoding residues 82-130 of SEQ ID NO:2 (SEQ ID NO:8), a segment encoding residues 18-310 of SEQ ID NO:2 (SEQ ID NO:9) or residues 82-130 of SEQ ID NO:2 (SEQ ID NO:10). Additionally, nucleic acids encoding a peptide consisting of or comprising the amino acid sequence of SEQ ID NOs:1, 23, 24, or 28.

The nucleic acid segments used in the present invention, regardless of the length of the coding sequence itself, may be combined with other nucleic acid sequences, such as promoters, enhancers polyadenylation signals, origin of replication, and a selectable marker gene, as well as other coding segments, and the like (all as are known to those of ordinary skill in the art), such that their overall length may vary considerably.

The term oligonucleotide refers to at least one molecule of between about 5 and about 100 nucleobases in length. These definitions generally refer to at least one single-stranded molecule, but in specific embodiments will also encompass at least one additional strand that is partially, substantially or fully complementary to the at least one single-stranded molecule. Thus, a nucleic acid may encompass at least one double-stranded molecule or at least one triple-stranded molecule that comprises one or more complementary strand(s) or “complement(s)” of a particular sequence comprising a strand of the molecule.

It is contemplated that the nucleic acid constructs of the present invention may encode full-length polypeptide from any source or encode a truncated version of the polypeptide, for example a truncated syndecan-1 polypeptide, such that the transcript of the coding region represents the truncated version. The truncated transcript may then be translated into a truncated protein. Alternatively, a nucleic acid sequence may encode a full-length polypeptide sequence with additional heterologous coding sequences, for example to allow for purification of the polypeptide, transport, secretion, post-translational modification, or for therapeutic benefits such as targeting or efficacy.

It is contemplated that the nucleic acid constructs of the present invention may regulate gene expression of an immunogenic polypeptide. A nucleic acid segment may regulate the expression of a full-length polypeptide sequence with additional heterologous coding sequences, for example to allow for therapeutic benefits such as targeting or efficacy.

In a non-limiting example, one or more nucleic acid constructs may be prepared that include a contiguous stretch of nucleotides identical to or complementary to a particular gene, such as the human syndecan-1 gene (SEQ ID NO:1), or a fragment thereof (SEQ ID NO:3 or that encoding SEQ ID NOs:8 or 9 or 10). Such a nucleic acid construct may be at least 20, 30, 40, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 160, 170, 180, 190, 200, 250, 300, 400, 500, 600, 700, 800, 900, 1000, 2000, 3000, 4000, 5000, 6000, 7000, 8000, 9000, 10000, 15000, 20000, 30000, 50000, 100000, 250000, 500000, 750000, to at least 1,000,000 nucleotides in length, as well as constructs of greater size, up to and including chromosomal sizes (including all intermediate lengths and intermediate ranges), given the advent of nucleic acids constructs such as a yeast artificial chromosome are known to those of ordinary skill in the art. It will be readily understood that “intermediate lengths” and “intermediate ranges,” as used herein, means any length or range including or between the quoted values (i.e., all integers including and between such values).

In certain other embodiments, the invention concerns isolated nucleic acid segments and recombinant vectors that include within their sequence a contiguous nucleic acid sequence from that shown in SEQ ID NO:1 or 3 or encoding SEQ ID NOs:8 or 9 or 10 or 21 or 23 or 28. This definition is used in the same sense as described above and means that the nucleic acid sequence substantially corresponds to a contiguous portion of that shown in SEQ ID NO:1 or 3 or encoding SEQ ID NOs:8 or 9 or 10 or 21 or 23 or 28 and has relatively few codons that are not identical, or functionally equivalent, to the codons of SEQ ID NO:1, 3 or encoding SEQ ID NOs:8 or 9 or 10 or 21 or 23 or 28. The term “functionally equivalent codon” is used herein to refer to codons that encode the same amino acid, such as the six codons for arginine or serine, and also refers to codons that encode biologically equivalent amino acids, as is known to those of skill in the art.

It also will be understood that this invention is not limited to the particular nucleic acid sequence of SEQ ID NO:1 and the amino acid sequence of SEQ ID NO:2. Recombinant vectors and isolated DNA segments may therefore variously include the syndecan-1-coding regions themselves, coding regions bearing selected alterations or modifications in the basic coding region, or they may encode larger polypeptides that nevertheless include syndecan-1-coding regions or may encode biologically functional equivalent proteins or peptides that have variant amino acids sequences.

The nucleic acid segments of the present invention encompass biologically functional equivalent syndecan-1 proteins and peptides. Such sequences may arise as a consequence of codon redundancy and functional equivalency that are known to occur naturally within nucleic acid sequences and the proteins thus encoded. Alternatively, functionally equivalent proteins or peptides may be created via the application of recombinant DNA technology, in which changes in the protein structure may be engineered,
The present invention also contemplates the use of tissue specific promoters and inducible promoters. Other promot-
er that may be employed with the present invention are constitutive and inducible promoters as are well known to
those of skill in the art. Additionally any promoter/enhancer combination (as per the Eukaryotic Promoter Data Base
EPDB) could also be used to drive expression of structural genes encoding oligosaccharide processing enzymes, pro-
tein folding accessory proteins, selectable marker proteins or a heterologous protein of interest.

B. Origins of Replication/Polyadenylation Signals

In expression, particularly eukaryotic expression, one will typically include a polyadenylation signal to effect proper
polyadenylation of the transcript. The nature of the polyadenylation signal is not believed to be crucial to the
successful practice of the invention. Polyadenylation signals include the SV-40 polyadenylation signal and the bovine
growth hormone polyadenylation signal, known to function well in various target cells. Polyadenylation may increase
the stability of the transcript or may facilitate cytoplasmic transport.

In order to propagate a vector in a host cell, it may contain one or more origins of replication sites (often termed “ori”),
which is a specific nucleic acid sequence at which replication is initiated. Alternatively an autonomously replicating
sequence (ARS) can be employed if the host cell is yeast.

C. Delivery of Nucleic Acids

Two broad approaches have been used to employ vectors to deliver nucleic acids to cells, namely viral vectors and
non-viral vectors. As by methods described herein and as is known to the skilled artisan, expression vectors may be
constructed to deliver nucleic acids segments encoding a syndecan-1 of the present invention to a organelle, cell,
tissue, or a subject. Such vectors comprising a syndecan-1 may be used in a variety of manner consistent with the
invention, including in screening assay and genetic immunization protocols.

A vector in the context of the present invention refers to a carrier nucleic acid molecule into which a nucleic acid
sequence of the present invention may be inserted for introduction into a cell and thereby replicated. A nucleic acid
sequence can be exogenous, which means that it is foreign to the cell into which the vector is being introduced; or that
the sequence is homologous to a sequence in the cell but positioned within the host cell nucleic acid in which the
sequence is ordinarily not found. Vectors include plasmids; cosmids; viruses such as bacteriophage, animal viruses, and
plant viruses; and artificial chromosomes (e.g., YACs); and synthetic vectors. One of ordinary skill in the art would be
well equipped to construct any number of vectors through standard recombinant techniques as described in Maniatis et
al., 1990 and Ausubel et al., 1994, incorporated herein by reference.

Viral vectors may be derived from viruses known to those of skill in the art, for example, bacteriophage, animal and
plant virus, including but not limited to, adenovirus, vaccinia virus (Ridgeway, 1988; Baichwal and Sugden, 1986;
Coupar et al., 1988) adenov-associated virus (AAV) (Ridgeway, 1988; Baichwal and Sugden, 1986; Hermonat and
Muzycska, 1984) retrovirus and herpesvirus and offer sev-

eral features for use in gene transfer into various mammalian
cells (Friedmann, 1989; Coupar, 1988; Baichwal and Sugden, 1986; Coupar et at., 1988; Horwich et al., 1990).
One of skill in the art would be well equipped to construct a vector through standard recombinant techniques as described in Sambrook et al. (2001), Maniatis et al. (1990) and Ausubel et al. (1994), incorporated herein by reference. The present invention may also employ non-viral vectors.

An expression vector refers to any type of genetic construct comprising a nucleic acid coding for a RNA capable of being transcribed. In the context of the present specification, expression vectors will typically comprise a nucleic acid segment encoding a syndecan-1 as described herein. In some cases, RNA molecules are then translated into a protein, polypeptide, or peptide. In other cases, these sequences are not translated, as in the case of antisense molecules or ribozymes production. Expression vectors can contain a variety of control sequences, which refer to nucleic acid sequences necessary for the transcription and possibly translation of an operably linked coding sequence in a particular host cell. In addition to control sequences that govern transcription and translation, vectors and expression vectors may contain nucleic acid sequences that serve other functions as well, and are described herein.

Non-viral vectors, such as plasmids and cosmids, require suitable method for delivery into cells. Such methods include, but are not limited to direct delivery of DNA by: injection (U.S. Pat. Nos. 5,994,624, 5,981,274, 5,945,100, 5,780,448, 5,736,524, 5,702,932, 5,656,610, 5,589,466 and 5,580,859, each incorporated herein by reference), microinjection (Harland and Weintraub, 1985; U.S. Pat. No. 5,789,215, incorporated herein by reference); electroporation (U.S. Pat. No. 5,384,253, incorporated herein by reference; Turkus et al., 1986; Potter et al., 1984); calcium phosphate precipitation (Graham and Van Der Eb, 1973; Chen and Okayama, 1987; Rippe et al., 1990); using DEAE-dextran followed by polyethylene glycol (Gopal, 1985); direct sonic loading (Fechheimer et al., 1987); by liposome-mediated transfection (Nicolaou and Sene, 1982; Fraley et al., 1979; Nicolaou et al., 1987; Wong et al., 1980; Kaneda et al., 1989; Kato et al., 1991); receptor-mediated transfection (Wu and Wu, 1987; Wu and Wu, 1988); microprojectile bombardment (PCT Application Nos. WO 94/06099 and 95/06128; U.S. Pat. Nos. 5,610,042, 5,322,783, 5,563,055, 5,550,318, 5,538,877 and 5,538,880, and each incorporated herein by reference); agitation with silicon carbide fibers (Kaeppler et al., 1990; U.S. Pat. Nos. 5,502,523 and 5,464,765, each incorporated herein by reference); desiccation/inhibition-mediated DNA uptake (Potrykus et al., 1985), and any combination of such methods. Through the application of techniques such as these, organelle(s), cell(s), tissue(s) or organism(s) may be stably or transiently transformed. In certain embodiments, acceleration methods are preferred and include, for example, microprojectile bombardment or inhalation methods.

Also in context of the present invention, topical delivery of a nucleic acid segment encoding a syndecan-1 to the skin may further comprise vesicles such as liposomes, niosomes and transferosomes thereby enhancing topical and transdermal delivery. Cationic lipids may also be used to deliver negatively charged nucleic acids. Sonophoresis or phonophoresis which involves the use of ultrasound to deliver the nucleic acid of interest, may also be employed for transdermal delivery. Ionophoresis which consists of applying a low electric field for a period of time to the skin may also be applied in delivering the nucleic acid of interest to the skin.

VI. Pharmaceutical Formulations, Delivery, and Cancer Treatment Regimens

In particular embodiments of the present invention, a method of treatment for cancer by the delivery of a Sdc-1 peptide or polypeptide (as described elsewhere in this document) is contemplated. Cancers contemplated by the present invention include, but are not limited to, breast cancer, lung cancer, head and neck cancer, bladder cancer, bone cancer, bone marrow cancer, brain cancer, colon cancer, esophageal cancer, gastrointestinal cancer, gum cancer, kidney cancer, liver cancer, nasopharynx cancer, ovarian cancer, prostate cancer, skin cancer, stomach cancer, testis cancer, tongue cancer, or uterine cancer. In particular embodiments, carcinomas, myelomas, melanomas or gliomas may be treated. A variety of other non-cancer angiogenic diseases may also be treated with the Sdc-1 peptides or proteins of the present invention. These include angiogenesis leading to abnormos of the vasculature (atherosclerosis and hemangiomas), of the eye (diabetic retinopathy and retinopathy of prematurity), the skin (pyogenic granulomas, porokeratosis, warts, scurfy keratosis, allergic granuloma), the mammary and ovary (dysfunctional uterine bleeding, follicular cysts, endometriosis, pre-eclampsia) adipose tissue (obesity), bones and joints (Rheumatoid arthritis, osteophyte formation), and AIDS-related pathologies resulting from TAT protein of the human immunodeficiency virus (HIV) activating the avb3 integrin on endothelial cells (Carmeliet and Jain, 2000; Urbinati et al., 2005).

A. Administration

To inhibit angiogenesis in, e.g., cancer, one would generally contact a cell or tissue that has or can promote or undergo angiogenesis, with a Sdc-1 peptide or protein or an expression construct encoding a Sdc-1 peptide or protein. The preferred method for the delivery of a peptide or an expression construct is via injection. Administration may be parenteral, intradermal, intramuscular, or intratumoral administration. Other administration routes include lavage, continuous perfusion, topical and oral administration and formulation. See U.S. Pat. Nos. 5,543,158; 5,641,515; 5,656,610; 5,589,466 and 5,390,363 (each specifically incorporated herein by reference in its entirety). Injection of nucleic acid constructs of the present invention may be delivered by syringe or any other method used for injection of a solution, as long as the expression construct can pass through the particular gauge of needle required for injection. A needleless injection system (U.S. Pat. No. 5,846,233); or a syringe system for use in gene therapy (U.S. Pat. No. 5,846,225), all as incorporated herein by reference, may be employed in the present invention.

B. Compositions and Formulations

Pharmaceutical forms suitable for injectable use include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions (U.S. Pat. No. 5,466,468, specifically incorporated herein by reference in its entirety). In all cases the form must be sterile and must be fluid to the extent that easy syringability exists. Composition(s) of absorption delay agents (aluminum monostearate and gelatin) may also be used. It must be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms, such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyl (e.g., glycerol, propylene glycol, and liquid polyethylene glycol, and the like), suitable mixtures thereof, and/or vegetable oils. Proper fluidity may be maintained, for example, by the use of a coating, such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. The prevention of the action of microorganisms can be brought about by various antibacterial and antifungal.
agents, for example, parabens, chlorobutanol, phenol, sorbic acid, thimerosal, and the like.

For parenteral administration in an aqueous solution, for example, the solution should be suitably buffered if necessary and the liquid diluent first rendered isotonic with sufficient saline or glucose (see for example, "Remington’s Pharmaceutical Sciences” 15th Edition, pages 1035-1038 and 1570-1580). These particular aqueous solutions are especially suitable for subcutaneous, intramuscular, and intraturnal administration. In this connection, sterile aqueous media that may be employed will be known to those of skill in the art in light of the present disclosure. Variation in dosage will necessarily occur depending on the condition of the subject being treated; the severity of the condition, and will be determined by the person administering the dose. For human administration, preparations should meet sterility, pyrogenicity, general safety and purity standards as required by FDA Office of Biologics standards.

The compositions of the present invention may be formulated in a neutral or salt form. Pharmaceutically-acceptable salts, include the acid addition salts (formed with the free amino groups of the protein) and which are formed with inorganic acids; or salts (formed with the free carboxyl groups) derived from inorganic bases as is known to those of ordinary skill in the art.

As used herein, “carrier” includes any and all solvents, dispersion media, vehicles, coatings, diluents, antibacterial and antifungal agents, isotonic and absorption delaying agents, buffers, carrier solutions, suspensions, colloids, and the like. The use of such media and agents for pharmaceutical active substances is well known in the art. Except insofar as any conventional medium or agent is incompatible with the active ingredient, its use in the therapeutic compositions is contemplated. Supplementary active ingredients can also be incorporated into the compositions. The phrase “pharmacologically-acceptable” or "pharmacologically-acceptable" refers to molecular entities and compositions that do not produce an allergic or similar untoward reaction when administered to a human. The preparation of an aqueous composition that contains a protein as an active ingredient is well understood in the art.

C. Combination Treatments

In the context of the present invention, it is contemplated that Sdc-1 peptides, proteins or analogs thereof may be used in combination with an additional therapeutic agent to more effectively treat a cancer or other angiogenic diseases.

Additional therapeutic agents contemplated for use in combination with Sdc-1 peptides, proteins or analogs thereof include, in the case of cancers, traditional anticancer therapies. Anticancer agents may include but are not limited to, radiotherapy, chemotherapy, gene therapy, hormonal therapy, surgery or immunotherapy that targets cancer/tumor cells.

To kill cells, induce cell-cycle arrest, inhibit migration, inhibit metastasis, inhibit survival, inhibit proliferation, or otherwise reverse or reduce the malignant phenotype of cancer cells, using the methods and compositions of the present invention, one would generally contact a cell with sdc-1 peptides, proteins or an analog thereof in combination with an additional therapeutic agent. These compositions would be provided in a combined amount effective to inhibit cell growth and/or induce apoptosis in the cell.

For other angiogenic diseases, the combination therapy may include administration of a second anti-angiogenic therapy. This process may involve contacting the cells with Sdc-1 peptides, proteins or analogs thereof in combination with an additional therapeutic agent or factor(s) at the same time. This may be achieved by contacting the cell with a single composition or pharmacological formulation that includes both agents, or by contacting the cell with two distinct compositions or formulations, at the same time, wherein one composition includes the Sdc-1 peptides, proteins or derivatives thereof and the other includes the additional agent.

Alternatively, treatment with Sdc-1 peptides, proteins or analogs thereof may precede or follow the additional agent treatment by intervals ranging from minutes to weeks. In embodiments where the additional agent is applied separately to the cell, one would generally ensure that a significant period of time did not expire between the time of each delivery, such that the agent would still be able to exert an advantageously combined effect on the cell. In such instances, it is contemplated that one would contact the cell with both modalities within about 12-24 hr of each other and, more preferably, within about 6-12 hr of each other, with a delay time of only about 12 hr being most preferred. Thus, therapeutic levels of the drugs will be maintained. In some situations, it may be desirable to extend the time period for treatment significantly (for example, to reduce toxicity). Thus, several days (2, 3, 4, 5, 6 or 7) to several weeks (1, 2, 3, 4, 5, 6, 7 or 8) may lapse between the respective administrations.

It is also conceivable that more than one administration of either syndecan-1 peptides or analogs thereof in combination with an additional anticancer agent will be desired. Various combinations may be employed, where Sdc-1 peptide, protein or an analog thereof is “A” and the additional therapeutic agent is “B”, as exemplified below:

Other combinations are contemplated.

VIII. Examples

The following examples are included to demonstrate preferred embodiments of the invention. It should be appreciated by those of skill in the art that the techniques disclosed in the examples which follow represent techniques discovered by the inventor to function well in the practice of the invention, and thus can be considered to constitute preferred modes for its practice. However, those of skill in the art should, in light of the present disclosure, appreciate that many changes can be made in the specific embodiments which are disclosed and still obtain a like or similar result without departing from the spirit and scope of the invention.

Example 1—Materials and Methods

Cells.

Human dermal microvascular endothelial cells (HMEC-1) and human aortic endothelial cells (HAEC) were grown in endothelial cell growth medium supplemented with 10% FBS serum. B82L mouse fibroblasts and human mammary carcinoma MDA-MB-231 cells were cultured in Dulbecco’s Modified Eagle’s medium supplemented with 10% FBS (Beauvais and Rapraeger, 2003; Beauvais et al., 2004; McQuade et al., 2006).

Recombinant mScd-1ED and Synstatin Inhibitors.

A GST fusion protein consisting of the mScd-1ED (amino acids 18-251) was used as a competitor in cell adhesion
studies (Beauvais and Rapraeger, 2003; McFall and Rapraeger, 1998). The protein was expressed in bacteria and purified on a glutathione affinity column as described in previous publications (Beauvais and Rapraeger, 2003; McFall and Rapraeger, 1998). Synstatin_{82-130} peptide represents amino acids 82-130 of mouse Sdc-1. The peptide was synthesized and purified to 75% purity by GenScript Corporation (Piscataway, N.J.).

Cell Spreading Assays.

Cell adhesion and spreading assays were performed with modification to the previous procedures (Lebakken and Rapraeger, 1996). Briefly, human plasma vitronectin or fibronectin at 10-30 µg/ml were applied to nitrocellulose-coated ten well slides (Erie Scientific) and incubated for 1-2 h at 37°C. Slides were blocked with 1% heat-denatured bovine serum albumin for a minimum of 30 min at 37°C. Cells were detached from the substratum using 5 mM EDTA in Tris-buffered saline and resuspended in HEPES-buffered culture medium containing 0.1% heat-denatured BSA. Cells were plated at a density of 15,000 cells per well and allowed to attach and spread for 2 h prior to fixation in 4% paraformaldehyde in CMF-PBS. For fluorescence microscopy, fixed cells were permeabilized in 0.2% Triton X-100, labeled with rhodamine-conjugated phallolidin and analyzed using fluorescence microscopy. For testing inhibition by recombinant mScd-1ED and synstatin_{82-130}, cells were pre-incubated 10 min before plating in the presence of the inhibitor. In addition, dependence on the α_β3 and α_β2 integrins for adhesion and spreading on VN was demonstrated using blocking antibodies specific for these integrins. Monoclonal Ab13, which blocks all β_1-containing integrins, was used to show that cell attachment and spreading was not dependent on αvβ4 integrin. LM609 was used as a specific block to αvβ5 integrin and P1F6 was used as a specific blocker of αvβ3 integrin.

siRNA Design and Transfection.

Human specific siRNA against Sdc-1 was transfected into HAECs at a range of concentrations up to 200 nM. At 4 h after transfection, each well was supplemented with 3 mL of complete growth medium; at 24 h post-transfection the cells were lifted in trypsin and expanded in 100 mm tissue-culture plates. Cohorts were detached with EDTA 24 h later, resuspended in 100 µL HEPES-buffered DME supplemented with 10% FBS and subjected to FACs analysis using mAb B-B4 specific for human Sdc-1 and an Alexa-488 conjugated anti-mouse secondary antibody. Cells were analyzed at the University of Wisconsin Comprehensive Cancer Center Flow Cytometry Facility using a FACSCalibur benchtop cytometer (BD Biosciences). Cell scatter and propidium iodide (Sigma, 1 µg/sample) staining profiles were used to gate live, single-cell events for data analysis.

Sdc1 and Integrin Expression in Mouse Tissues.

Frozen sections of normal mouse artery, or tumors arising in the mammary gland of transgenic mice expression the Wnt oncogenes under control of the mammary gland specific MMTV-promoter were fixed and stained with a rabbit polyclonal antibody specific for Sdc1 and a rat monoclonal antibody specific for the endothelial cell marker PECAM. Tissues were also stained with rabbit polyclonal antibodies to the mouse αv integrin subunit (AB1930), the mouse β3 integrin subunit (AB1932) or the mouse β5 integrin subunit (AB1926). Non-specific control rabbit or rat IgGs were used to demonstrate specificity. The primary antibodies were stained with Alexa488- or Alexa548-conjugated secondary antibodies and distribution of the receptors in the tissue observed via fluorescence microscopy.

Corneal Pocket Implant Angiogenesis Assay.

A polyhydroxethylmethacrylate (PolyHEMA) pellet 1 µl in volume containing 100 ng FGF was implanted into pockets surgically prepared in the center of the avascular corneas of 6 wk-old Balb/c mice. Three mice were used as controls and three mice received a 0.2 ml Alzet osmotic pump implanted subcutaneously on the back of the mice. The pump was loaded with 100 µM synstatin_{82-130} in sterile saline and delivers 1 µl into the mouse per hr. The mice were allowed to recover and were maintained for seven days. The extent of angiogenesis was recorded by digital camera images of the living mouse. Fluorescent dextran was then injected into the vascular via retro-orbital injection 1-2 minutes prior to sacrifice. Corneas were surgically removed, mounted on slides and the extent of vascularization observed via fluorescence microscopy.

Example 2—Results

Regulation of αvβ4 and αvβ5 Integrin Activity on Endothelial Cells by Recombinant Syndecan-1 Ectodomain.

There has not been a concerted examination of Sdc-1 expression in vascular endothelium. Most reports suggest that it is expressed poorly or not at all on resting, mature vascular endothelium that line blood vessels. However, there are reports that it is expressed on activated endothelial cells participating in angiogenesis in the wounded skin (Elenius et al., 1991; Gallo et al., 1996). Sdc-1 is not expressed in endothelial cells lining the rabbit aorta, but expression is upregulated following balloon catheter injury and persists for up to 12 weeks following injury. There is a report that Sdc-1 is upregulated in a subset of vessels during tumor angiogenesis (Gott et al., 2002). These studies strongly suggest that Sdc-1 becomes expressed on activated cells responding to injury or growth factors. Cultured cells, such as human aortic and human umbilical vein endothelial cells reportedly show expression of Sdc-1 at the mRNA level (Mertens et al., 1992), although, as the inventors note above, the expression patterns described may be dependent on the growth factors and supplements, such as brain extract, added to the culture medium.

The inventors have now examined the expression of Sdc1 on several types of cultured endothelial cells. Flow cytometry or Western blot analysis of cells shows that human aortic endothelial cells (HAECs), human dermal microvascular endothelial cells (HMEC-1s), mouse aortic endothelial cells, mouse brain endothelial cells and mouse heart endothelial cells have a significant cell surface population of αvβ3 and αvβ5 integrins. The inventors examined the expression of αvβ3 integrin in the angiogenic vasculature of mouse tumors. The inventors examined mammary carcinomas arising in mice that co-express either the Wnt-1 oncogene or the β-catenin oncogene. Staining for Sdc1 showed that it is highly expressed in the angiogenic tumor vasculature of both tumors, and is co-expressed at this site with the αvβ3 and αvβ5 integrins (FIG. 1). This is in contrast to a normal mouse artery endothelium which shows little expression of any of these three receptors (FIG. 1).

The inventors have examined the Sdc1 regulation of the αvβ3 and αvβ5 integrins in several types of endothelial cells. Human aortic endothelial cells (HAEC) express abundant amounts of the αvβ3 integrin and somewhat less of the αvβ5. The cells also express a high level of the β1 integrin subunit, which is capable of assembling with the αv subunit to form the αvβ1 integrin. All three of these integrins are
potential vitronectin receptors and it is thus not surprising that these endothelial cells bind and spread on vitronectin. To assess the actual contribution of each integrin, the inventors have plated the cells on vitronectin in the presence of inhibitory antibodies to the β3 integrins (mAb13), the αvβ3 (LM609) and the αvβ5 (P1F6). The inventors find that inhibiting the αvβ1 integrin has little or no effect, but that the HAECs fail to attach and spread normally on VN when both the αvβ3 and αvβ5 are inhibited (Fig. 2).

The next test was whether agents that target Sdcl, especially competition with recombinant SIED, will block the activity of these two integrins and thus block their interaction with VN. The inventors find that, indeed, the HAEC cell spreading on VN is blocked by the soluble SIED at a concentration similar to that of the αvβ3 in mammary carcinoma (Beauvais and Rapraeger, 2003) and that of the αvβ5 (Beauvais et al., 2004). Recombinant Sdcl ectodomain (SIED) has been shown by the inventors previously to block spreading of these cells with an IC50 of about 3-10 µM (Beauvais et al., 2004). In contrast, the inventors find that synstatinb2-130 has an IC50 of about 0.1 µM, indicating that it is about 30-100x more effective (Fig. 5). A 1 µM concentration of synstatinb2-130 completely blocks cell attachment, an outcome that the inventors have not seen with the highest concentrations of recombinant SIED tested (50 µM). As a control, the inventors tested cell adhesion and spreading on fibronectin, a ligand on which the cells use the αβ1 integrin and do not rely on the αvβ3 integrin; synstatinb2-130 has no effect on attachment and spreading on this ligand (Fig. 5). Thus, synstatinb2-130 is a specific and effective inhibitor of αvβ5 integrin activation.

Similar findings are observed with B82L fibroblasts (Fig. 6). The inventors have shown previously that these cells rely solely on the αvβ5 integrin to recognize VN, and that this recognition also depends on activation of the integrin by Sdcl (McQuade et al., 2006). Recombinant Sdcl affects this process with an IC50 of ca. 3-10 µM, similar to its inhibition of αvβ5 integrin activation in the carcinoma cells (McQuade et al., 2006). Synstatinb2-130 disrupts the spreading of the B82L cells on VN with an IC50 of ca. 0.1 µM, and completely blocks any cell attachment at 1 µM.

Finally, the inventors have examined HMEC-1 cells, which are immortalized human dermal microvascular endothelial cells. Microvascular endothelial cells are regarded as being the main source of endothelial cells that carry out angiogenesis in vivo. The HMEC-1 cells grown in serum-containing culture medium express Sdcl (as noted earlier) and also express active αvβ3 and αvβ5 integrins. The inventors find using inhibitory antibodies to the αvβ3 and/or αvβ5 integrins that the HMEC-1 cells attachment to VN is dependent on these two integrins and both must be inhibited to disrupt attachment and spreading on this ligand (not shown), similar to the analysis shown for the HAECs in Fig. 2. Recombinant SIED blocks the spreading on VN with an IC50 of 3-10 µM, similar to its disruption of αvβ3 and/or αvβ5 integrins in the mammary carcinoma and B82L cells (Beauvais and Rapraeger, 2003; Beauvais et al., 2004; McQuade et al., 2006). Synstatinb2-130 is again more effective, disrupting spreading with an IC50 of approximately 0.1 µM (Fig. 6). Thus, the peptide inhibitor synstatinb2-130 derived from the native sequence of Sdcl is a highly effective inhibitor of these two integrins on endothelial cells as well as other cells that rely on either of these two integrins.
Inhibition of Angiogenesis In Vivo by Disrupting the Sdc1 Regulation of avβ3 and avβ5 Integrins.

To test the efficacy of synstatin82-130 in vivo, the inventors have used the mouse corneal pocket implant angiogenesis assay. Here, angiogenesis is induced in the avascular mouse cornea by implantation of a polyHEMA pellet containing fibroblast growth factor (FGF), which is a potent angiogenic agent. The FGF will induce angiogenic outgrowth of new vessels from the limbal vessels at the margin of the cornea into the avascular region at the center of the cornea where the pellet is implanted. The inventors have tested recombinant S1ED by supplying it along with the FGF in the pellet implanted into the cornea, and have also introduced it into the systemic circulation of the mouse through the use of an osmotic pump placed subcutaneously on the back of the animal. The latter protocol more closely mimics the manner in which such an inhibitor might be delivered as a drug in patients. In both circumstances recombinant S1ED blocks the FGF-induced angiogenesis. The concentration necessary for the block in vivo has not yet been measured. It is supplied at a concentration of 2.4 mM in the osmotic pump, which delivers 1 µl into the mouse per hour; if the inventors assume that it is contained within the 2 ml blood volume of the mouse, and assume that there is no protein degradation or clearance, then it would achieve concentrations of approximately 29 µM after 24 hr. However, this is likely to be a high estimate, as clearance and degradation are likely to occur, and the protein is likely to be present in the greater volume of the mouse than just the vascular system. Thus, the recombinant protein may be highly effective in vivo at concentrations of 29 µM or less.

The inventors have tested synstatin82-130 in the corneal angiogenesis protocol as well, delivering it into the mouse circulation via the osmotic pump as described for S1ED. The starting concentration in the pump is 100 µM, 24-fold lower than S1ED; using the same assumptions and caveats as noted for pump delivery of recombinant S1ED, the systemic concentration of the inhibitor may reach 1.2 µM after 24 hr. Again, this is likely to be a high estimate. In six mice tested to date, the inventors have seen a complete inhibition of angiogenesis via systemic delivery of synstatin82-130. Control mice containing the FGF implant show extensive vessel outgrowth extending from the limbus vessel at the perimeter of the cornea to the pellet in the center, where the new angiogenic vessels engulf the FGF pellet (FIG. 7). In mice with systemically-delivered synstatin82-130 the mice show no angiogenesis (FIG. 7). The inventors have not yet tried lower concentrations. It should be emphasized that following the one week of treatment with this concentration of inhibitor that is highly effective against angiogenesis, these mice show no ill effects. They are active, eat normally, maintain weight and show no altered behavior.

Example 3

Introduction

Angiogenesis, or the sprouting of new blood vessels from existing ones, occurs in development and in diseases such as diabetic retinopathy, endometriosis, and tumor-induced angiogenesis. The mature, resting endothelial cells in the donor vessels are activated to progress through an angiogenic program, in which they undergo proliferation and invasion, maturation, and apoptosis; the latter, also known as “vascular pruning” is especially important in molding the architecture of the new vessels (Bergers and Benjamin, 2003; Stupack and Cheresh, 2003).

FGF and VEGF, two growth factors often released by tumors, are potent angiogenic factors. Their activities are closely tied to the activity of two integrins, the αβ3 and αβ5 integrins (Stupack and Cheresh, 2003), which have roles in the chemotactic migration and in the survival of the endothelial cells. The expression of these two integrins is induced by FGF and VEGF signaling and the integrins and growth factor receptors then collaborate in the signaling pathways leading to angiogenesis. Uncoupling of this signaling by inactivation of either type of receptor leads to apoptosis of the endothelial cells (Stupack et al., 2001) and this mechanism is believed to have a major role in vessel pruning as the new vasculature acquires its final architecture. The αβ3 and αβ5 integrins are not generally expressed in adult cells, with the exception of a few sites such as osteoclasts, but their expression on activated endothelial cells during angiogenesis (Bryzova et al., 1998) as well as in many tumors during metastasis, makes them attractive targets for combating tumorigenesis. A choice target is their apoptotic role, as triggering apoptosis of the endothelial cells will starve the tumors that require a new vascular supply for nutrient and gaseous exchange. Indeed, this apoptotic role of the integrin may explain why β3 and β5 knockout mice exhibit increased angiogenesis, whereas inhibitors of the αβ3 and αβ5 integrins in normal mice are anti-angiogenic; it is hypothesized that potent apoptotic signaling arises from these integrins when they are inhibited in wild-type mice, whereas the integrin null mice are freed from this apoptotic mechanism (Bader et al., 1998; Reynolds et al., 2002).

The activation of an integrin typically refers to a conformation change that allows ligand binding. The αβ3 has been used as a model to understand this activation mechanism. It proceeds through at least two activation states, each resulting in a change in conformation of the extracellular domain in response to intracellular signals and extracellular ligand binding (Boettiger et al., 2001; Boettiger et al., 2001; Du et al., 1991; Fredinger et al., 1991; Humphries, 1996; Liddington and Ginsberg, 2002; Pelletier et al., 1996; Plow et al., 2000; Xiong et al., 2001; Yan et al., 2000). “Activating” or “inactivating” antibodies directed to the integrin extracellular domain cause to form it to one or the other conformation. One such antibody, LM609, freezes the αβ3 integrin in the inactive conformation, blocks angiogenesis and leads to endothelial cell apoptosis. A humanized version of this antibody (Vitaxin) is in clinical trials as an antitumor agent.

The syndecans are multifunctional matrix receptors on the surface of all adherent cells. They anchor to the matrix via heparan sulfate glycosaminoglycan chains and communicate to the cytoplasm via short but highly conserved cytoplasmic domains. The heparan sulfate chains have important signaling properties, as they enhance the assembly of growth factor with their receptor tyrosine kinases. However, it is becoming clear that the synde can proteins have important regulatory roles as well, often leading to the description of this family as “co-receptors,” as they assemble with and control the signaling of other receptors on the cell surface. Several reports now indicate that specialized sites may exist within the syndecan extracellular protein domains, which if mutated or targeted with antibodies, disrupt tumor cell invasion. If true, such sites may hold promise as targets for therapeutic drugs to combat tumorigenesis.

Syndecan-1 Associates with the αβ3 and αβ5 Integrins, and this Association is Disrupted by SSTN.

The inventors have described a role for syndecan-1 in regulating activation of the αβ3 integrin in human mammary carcinoma cells, and the αβ5 integrin in B82L mouse
fibroblasts. This regulation involves a site in the extracellular domain of syndecan-1, demonstrated in human MDA-MB-231 or MB-435 mammary carcinoma cells, which utilize the αβ3 integrin to bind, spread or migrate on vitronectin. Integrin activity is abolished by silencing syndecan-1 expression with human-specific siRNA, and is rescued by re-expressing mouse syndecan-1; however, deletion mutants lacking a region of the extracellular domain encompassing amino acids 88-121 in the mouse sequence fail to rescue (FIG. 8A). This sequence has a high degree of conservation across mouse, hamster, rat and human syndecan-1 (FIG. 9).

Because syndecan-1 regulates both of these integrins that are attractive targets for anti-angiogenic therapy, the inventors questioned whether this regulatory mechanism existed on endothelial cells. Although some reports indicate that syndecan-1 is not expressed on vascular endothelium (Elenius et al., 1991; Gallo et al., 1996; Hayashi et al., 1987; Kainulainen et al., 1996), other reports suggest that it is upregulated on activated endothelial cells undergoing angiogenesis (Elenius et al., 1991; Gallo et al., 1996; Gotte et al., 2002; Kainulainen et al., 1996). The inventors examined the expression of syndecan-1 and the two integrins on three lines of vascular endothelial cells by flow cytometry (FIG. 8B). Human aortic endothelial cells and human dermal microvascular endothelial cells all express modest levels of syndecan-1 and a larger population of the αβ3 and αβ2 integrins. Mouse aortic endothelial cells express higher levels of syndecan-1 than their human counterparts, but less of the αβ3 integrin. Although a reliable antibody for detecting the mouse αβ3 integrin by flow is not available, it can be shown that they also express the αβ3 integrin by western blot, shown in comparison to B82L fibroblasts (FIG. 8B), known to express this integrin.

To determine if the syndecan and integrins are in a regulatory complex, plots containing syndecan-1 immunoprecipitated from HMECs were probed for the co-precipitation of the β3 and β2 integrin subunits; this is indicative of an association of the syndecan with the αβ3 and αβ2 integrins. Mouse aortic endothelial cells express higher levels of syndecan-1 than their human counterparts, but less of the αβ3 integrin. Although a reliable antibody for detecting the mouse αβ3 integrin by flow is not available, it can be shown that they also express the αβ3 integrin by western blot, shown in comparison to B82L fibroblasts (FIG. 8B), known to express this integrin.

Syndecan-1 is Expressed During Angiogenesis.

The αβ3 and αβ2 Integrin on Vascular Endothelial Cells is Regulated by Syndecan-1.

The inventors next questioned whether SSTN is inhibitory to integrin activation. HMECs plated on a substratum consisting solely of a monoclonal antibody (B-14) to syndecan-1 attach to the antibody and spread. Their prior work has suggested that the cell spreading requires integrin activation and signaling. Indeed, the αβ3 integrin on the cell is activated, detected by staining the cells with the ligand-mimetic antibody WOW-1 (FIG. 10A); this antibody binds only to activated integrin. However, co-incubation of the cells with 0.5 µM SSTN prevents both the cell spreading and recognition by WOW-1, indicating that competitive displacement of the integrin from the ligated syndecan prevents integrin activation. Identical results are seen in the converse experiment, namely plating the cells on vitronectin, a ligand for both the αβ3 and αβ2 integrins. The spreading of the cells is dependent on both integrins; spreading is blocked in the presence of antibodies LM609 and P1F6 (FIG. 10A), which inactive the αβ3 and αβ2 integrins, respectively, but is not blocked in the presence of either antibody alone (not shown). However, addition of either 5.0 µM recombinant mS1ED or 0.5 µM SSTN blocks spreading as effectively as the combined antibody treatment (FIG. 10A). An identical result is obtained if syndecan-1 expression is silenced with siRNA (FIG. 10B). Both findings support the conclusion that syndecan-1 is simultaneously regulating the activation of both integrins in vascular endothelial cells.

The effective inhibitory concentration of SSTN is lower than that of the recombinant mS1ED protein. This is shown using either HMECs or human aortic endothelial cells plated on vitronectin and quantifying cell spreading (FIG. 10C) or cell attachment (FIG. 10D). Competition with mS1ED at 1-3 µM concentrations reduced cell spreading by over 80-90%, respectively for the HMECs, and displays at IC50 of about 1 µM for HAECS, which are more resistant than the HMECs. Complete integrin inactivation necessary for blocking cell attachment altogether requires over a 10-fold higher concentration of 10 µM. In comparison, SSTN displays inhibitory activity equal to that of mS1ED when used at a 10-fold lower concentration and has significant inhibitory properties in the 0.1-0.3 µM range. At this concentration it is equal or more effective than 10 µg/ml of the inhibitory antibodies LM609 and P1F6. Although the reason for the greater inhibition by SSTN is not known, it may trace to misfolding of the mS1ED protein when expressed in bacteria, or it may indicate that the SSTN sequence in the full ectodomain is partially hidden. Computer modeling of the syndecan or SSTN sequence is not reliable as the proteins have little or no homology to any proteins that have been crystallized to date.

Syndecan-1 is Expressed During Angiogenesis.

To test the activity of SSTN as an anti-angiogenic agent, the inventors turned to the in vitro aortic ring outgrowth assay and the in vivo corneal angiogenesis model. The aortic outgrowth assay allows quantification of microvessel outgrowth from segments of mouse aorta explanted to type I collagen gels. As was found when examining the mouse aortic endothelial cell line in culture, both syndecan-1 and the αβ3 and αβ2 integrins appear present even on the resting mouse aorta (FIG. 11A). In addition, microvessels growing out from the aortic explant over a 7 days period in response to FGF stain positively for syndecan-1, with appears co-expressed with the αβ3 and αβ2 integrins (FIG. 11B).
To extend this finding of syndecan-1 expression in activated endothelium, the inventors also examined two models of mouse breast tumor formation. Tumors derived from wnt-1 overexpression in the mammary gland show a high degree of vascularization, identified as internal networks lined by a thick cell layer than stains intensely for syndecan-1 and for PECAM (CD31), indicative of activated endothelium (FIG. 11C). In fact, syndecan-1 expression in these cells swamps out the positive staining for syndecan-1 seen in the mammary epithelial cells, which are known to be positive for syndecan-1. These same cell layers as positive for \( \alpha_v, \beta_3 \) and \( \alpha_v, \beta_5 \) integrin subunits. A similar finding is seen in tumors arising from overexpression of \( \beta\)-catenin (FIG. 11C). Although the vascularization is not as extensive as in the \( \beta\)-catenin-induced tumors, there are clear thickened layers of cells that are PECAM, syndecan-1 and \( \alpha_v, \beta_3, \alpha_v, \beta_5 \) integrin positive in these mammary tumors.

SSTN Inhibits Angiogenesis In Vitro and In Vivo.

To test the effect of SSTN on microvessel outgrowth, segments of thoracic aorta were explanted to collagen gels in the presence of either 50 ng/ml vascular endothelial cell growth factor (VEGF) or 30 ng/ml FGF-2, and incubated in the presence of either recombinant mSlED or SSTN. Although some vessel outgrowth is observed in the absence of exogenous angiogenic agents, likely due to VEGF release by supporting cells growing out from the explant, the outgrowth is greatly (\( \approx 10\)-fold) increased by FGF or VEGF (FIG. 12). Addition of recombinant mSlED blocks VEGF-induced outgrowth by more than 70\% at 10 \( \mu\)M, and greater than 95\% at 30 \( \mu\)M. FGF-induced outgrowth requires slightly higher inhibitory concentrations (approximately 30 \( \mu\)M mSlED for 70\% inhibition), which may trace to a difference in susceptibility of the two integrins, as VEGF signaling is reportedly coupled to \( \alpha_v, \beta_3 \) integrin activation and FGF signaling is coupled to \( \alpha_v, \beta_5 \) activation. SSTN is 10-fold more potent as an anti-angiogenic agent, displaying an IC50 of 0.1 \( \mu\)M in FGF and a slightly greater IC50 in response to VEGF. These concentrations are much in line with the IC50’s displayed in the in vitro cell attachment and spreading assays with HMECs and HAEcs. It should be noted that the microvessel outgrowth is accompanied by the outgrowth of support cells, most likely smooth muscle cells and fibroblasts. These cells are not endothelial cells, as they do not stain positively for PECAM, and their outgrowth is unaffected by mSlED or SSTN (FIG. 12). Thus, the effects of SSTN are highly localized to the vascular endothelial cells.

Lastly, SSTN was tested in the in vivo corneal angiogenesis assay. Polyhydroxyethylmethacrylate pellets (0.25 \( \mu\)L) containing 67 ng FGF-2 and sucralate as a slow release agent were implanted into the avascular mouse cornea. After seven days, fluorescent dextran was injected suborbitally to highlight the vascular system and the mice were sacrificed. Visual inspection of either the eye or the dissected cornea reveals significant vessel ingrowth towards the implanted pellet from the limbus vessel at the margin of the cornea. Initial experiments found that incorporation of recombinant mSlED into the pellet reduced the angiogenesis (data not shown). To supply the inhibitor in a more quantifiable and physiological manner, recombinant mSlED or SSTN were delivered systemically via Alzet osmotic pumps implanted subcutaneously on the backs of the animals. Pumps containing either 2500 \( \mu\)M recombinant mSlED or 30 SSTN achieved a nearly total block of angiogenesis. Testing a range of SSTN concentration in the pump showed that 50\% inhibition of angiogenesis is achieved by 3-10 \( \mu\)M SSTN concentrations in the pump (FIG. 13). To correlate this with the active concentration in the plasma, the inventors took advantage of rabbit polyclonal antibodies generated against mSlED, which detect active SSTN on dot blots. The antibodies appear to recognize an active conformation of SSTN, as heating the peptide to 95°C causes it to lose its inhibitory activity and its recognition by antibodies on dot blots (data not shown). Using this method to detect active SSTN in the blood collected from animals after 1 week of SSTN treatment, SSTN is shown to be in the blood at 125-150 nM when present at 10 in the osmotic pump. This correlates well with the IC50 of ca. 0.1 \( \mu\)M observed in vitro and suggests a clearance rate of 10-13 hr in the plasma.

Effective Size of SSTN Peptide.

The SSTN peptide that we have used is SSTN82-130, based on the mouse sequence (cf. FIG. 9). This peptide spans the active site in mouse syndecan-1 and retains flanking amino acids on either side in case they are required to maintain structure. The peptide contains two adjacent regions in which the amino acids are highly conserved across species, suggestive of a conserved function (FIG. 14). Truncation of SSTN82-130 to smaller peptides that delete portions of these conserved sites cause loss of activity (FIG. 14). Thus, SSTN85-121, which retains one amino acid C-terminal and one amino acid N-terminal to the conserved domain is active, but SSTN88-117, which removes four of the conserved amino acids at the C-terminus is 3-fold less active in cell attachment and spreading assays on VN. Thus, it appears that the most active SSTN peptide is that which retains both of these conserved sequences.

Effects of SSTN on CAG Myeloma Tumor Formation In Vivo.

The inventors have introduced human CAG myeloma cells expressing luciferase into immunodeficient SCID mice and treated the mice either with SSTN or control PBS. 10\(^5\) cells were injected subcutaneously into the flanks of 10 animals and allowed to grow for 10 days. At this point, tumors have begun to form and can be detected by manual palpation or by imaging the luciferase-expressing tumor cells. Alzet pumps containing either PBS or 100 \( \mu\)M SSTN were implanted on the backs of the animals and the tumors allowed to grow for an additional 28 days. The pumps are 28-day pumps (unlike the 7-day pumps used for corneal angiogenesis assays) and delivered 0.25 \( \mu\)L of 100 \( \mu\)M SSTN per hr. This is roughly equivalent to the corneal angiogenesis assays in which the 7 day pumps deliver 1 \( \mu\)L of 30 \( \mu\)M SSTN per hr, which achieves significant inhibition of angiogenesis. After the 28 day treatment period, the tumors were again imaged in situ, indicating that the 5 control tumors were 10-11 times larger than tumors in the SSTN-treated animals (FIG. 15). The tumors were dissected and weighed, again showing that the SSTN reduced by tumor size by over 10-fold (FIG. 16). In addition, the SSTN-treated tumors appear pale, suggesting a lack of vascularization. Sectioning of the tumors and staining for mouse CD34, an endothelial cell marker, to monitor the ingrowth of host blood vessels into the human tumor shows a significant reduction in vessel density and vessel length. There is no positive staining using antibody specific for human CD34, indicating that the tumors are vascularized by host angiogenesis and that this is blocked by circulating SSTN.

Summary.

These results show that SSTN is an effective inhibitor of the \( \alpha_v, \beta_3 \) and \( \alpha_v, \beta_5 \) integrins both in vitro and in vivo. Syndecan-1 is expressed together with these integrins on activated endothelial cells undergoing angiogenesis in response to FGF and VEGF, or in tumors. The integrins
appear to rely on syndecan-1 to undergo activation, as blocking syndecan-1 expression, deleting the integrin activation site from the syndecan receptor, or, as shown here, competition with the interaction of the syndecan with the integrins using a peptide (SSTN) containing the syndecan active site, all serve to inactivate the integrins and block endothelial cell attachment, spreading, and angiogenesis. SSTN (or SSTN mimetics) is an attractive therapeutic to target and inactivate these two integrins on tumor cells, activated endothelial cells, osteoclasts, and other cells that depend on these integrins in disease processes.

Example 4

The synstatin (SSTN) peptides that were previously tested have been derived from the mouse syndecan-1 (Sdcl) sequence so that their biological activity can be tested in mouse models without eliciting an immune response. Nonetheless, the in vitro work with cell lines shows that both the mouse and human Sdcl have identical abilities to regulate the α1β1 and α3β5 integrins.

To test a human SSTN peptide, experiments were conducted with human SSTN with amino acids 88-121 of the human sequence (hSSTN 88-121) (SEQ ID NO:28) and amino acids 89-120 of the human sequence (hSSTN 89-120) (SEQ ID NO:21). The human and mouse Sdcl sequences differ in length by one amino acid counting from the amino terminus to the beginning of the SSTN sequence (human is longer by one amino acid), and therefore, it was desirable to test not only the 89-121 sequence, but also 89-120 to make sure that the difference of one amino acid on either end would not affect its activity.

In FIG. 17, both peptides show identical abilities to block the attachment and spreading of human MDA-MB-231 breast carcinoma cells to vitronectin (VN). The inventors have shown previously that this attachment and spreading is dependent on Sdcl activating the α1β1 integrin on these cells (Beauvais et al., 2004). Furthermore, the two peptides show an IC50 of 0.1 to 0.3 which is identical to the most active mouse SSTN peptides (mouse SSTN 82-130 or mouse SSTN 88-122.) The peptides have no effect on cell attachment and spreading on fibronectin (FN) when used at a concentration 100-fold greater than their IC50. The inventors have shown previously that this attachment and spreading on FN relies on the α1β1 integrin and is not dependent on Sdcl.

All of the compositions and/or methods disclosed and claimed herein can be made and executed without undue experimentation in light of the present disclosure. While the compositions and methods of this invention have been described in terms of preferred embodiments, it will be apparent to those of skill in the art that variations may be applied to the compositions and/or methods and in the steps or in the sequence of steps of the method described herein without departing from the concept, spirit and scope of the invention. More specifically, it will be apparent that certain agents which are both chemically and physiologically related may be substituted for the agents described herein while the same or similar results would be achieved. All such similar substitutes and modifications apparent to those skilled in the art are deemed to be within the spirit, scope and concept of the invention as defined by the appended claims.

<210> SEQ ID NO 27
<211> LENGTH: 14
<212> TYPE: PRT
<213> ORGANISM: Artificial
<220> FEATURE:
What is claimed is:

1. A method of treating a subject having a disease characterized by angiogenesis wherein the disease is not cancer, comprising contacting endothelial cells of the subject that express $\alpha_\text{v} \beta_3$ or $\alpha_\text{v} \beta_5$ integrin and are responsible for said angiogenesis with a peptide or polypeptide segment consisting of 32 to 100 amino acid residues and comprising SEQ ID NO:21, whereby the disease is treated.

2. The method of claim 1, wherein said peptide or polypeptide segment is 35, 40, 45, 49, 50, 55, 60, 65, 70, 75, 80, 85, 90, 95 or 100 amino acid residues in length.

3. The method of claim 1, wherein said peptide or polypeptide segment is 32 to 80 amino acid residues in length.

4. The method of claim 1, wherein said peptide or polypeptide segment is 32 to 50 amino acid residues in length.

5. The method of claim 1, wherein said peptide or polypeptide segment is 32 to 40 amino acid residues in length.

6. The method of claim 1, wherein said peptide segment consists of SEQ ID NO:10.

7. The method of claim 1, wherein said peptide segment comprises at least 35 contiguous amino acids from SEQ ID NO:10.

8. The method of claim 1, wherein said peptide segment consists of SEQ ID NO:28.

9. The method of claim 1, wherein said peptide segment consists of SEQ ID NO:21.

10. The method of claim 1, wherein said disease is selected from the group consisting of abnormalities of the vasculature, abnormalities of the eye, abnormalities of the skin, abnormalities of the uterus and ovary, abnormalities of the adipose tissue, abnormalities of the bones and joints, and AIDS-related pathologies resulting from TAT protein of the human immunodeficiency virus (HIV) activating the $\alpha_\text{v} \beta_3$ integrin on endothelial cells.

11. The method of claim 10, wherein said disease is selected from the group consisting of atherosclerosis, hemangiomas, diabetic retinopathy, retinopathy of prematurity, pyogenic granulomas, psoriasis, warts, scar keloids, allergic edema, ulcers, dysfunctional uterine bleeding, follicular cysts, endometriosis, pre-eclampsia, obesity, rheumatoid arthritis, and osteophyte formation.

12. The method of claim 1, wherein contacting comprises systemic administration of said peptide or polypeptide segment or administration of said peptide or polypeptide segment local to said endothelial cells.

13. The method of claim 1, wherein said peptide or polypeptide segment is active at 0.3 µM.

14. The method of claim 1, wherein said peptide or polypeptide segment is active at 0.1 µM.

15. The method of claim 1, further comprising contacting said endothelial cells with a second anti-angiogenic agent.
