(57) ABSTRACT

Novel extender units for Type I polyketide synthases are provided. Also provided are genes, compounds, and methods for generating these units, and for incorporation of the novel extender units into polyketides for the purpose of generating new structural derivatives of polyketide-containing products.

TYPE I POLYKETIDE SYNTHASE EXTENDER UNITS

CROSS-REFERENCE TO RELATED APPLICATIONS

This invention claims priority to U.S. Provisional Patent Application Ser. No. 60/923,105, filed Apr. 12, 2007, which is herein incorporated by reference.

GOVERNMENT INTERESTS

This invention was made with United States government support under grant No. A1065850 awarded by the NIH. The United States government has certain rights in this invention.¹⁵

FIELD OF THE INVENTION

The present invention is related to the field of polyketide synthases (PKSs) and extender units used in the synthesis of ²⁰ polyketide molecules. The present invention is also related to the field of PKS molecules capable of recognizing and incorporating particular PKS extender units into polyketide molecules.

BACKGROUND OF THE INVENTION

Polyketides are a class of compounds synthesized by the enzymatic polymerization of acetyl, proprionyl, butyryl and methoxyacetyl moieties (extender units) into a polyketide 30 backbone through a series of decarboxylative condensation and reduction reactions and subsequent modifications. Polyketide natural products biosynthesized by polyketide synthases have diverse biological activities such as antibacterial, antifungal, anticancer, and immunosuppressant activities. Many of these products play important roles in the treatment of a variety of human diseases.

The Type I polyketide synthases are highly modular proteins. Each Type I PKS module consists of several domains with defined functions, separated by short spacer regions. 40 Type I PKSs catalyze the biosynthesis of complex polyketides such as erythromycin and avermectin. These "modular" PKSs include assemblies of several large multifunctional proteins carrying, between them, a set of separate active sites for each step of carbon chain assembly and modi- 45 fication (Donadio et al., 1991, Science 252: 675-679; Mac-Neil et al., 1992, Gene 115: 119-125). The active sites required for one cycle of condensation and reduction are typically clustered as "modules". For example, 6-deoxyerythronolide B synthase (DEBS) consists of the three mul- 50 tifunctional proteins, DEBS 1, DEBS 2, and DEBS 3, each of which possesses two modules that incorporate an extender unit into a polyketide chain (Caffrey et al., 1992, FEBS Lett. 304: 225-228).

The diverse activities of polyketides are partly due to their 55 extensive structural diversity available via Type I PKS enzymology (FIG. 1). However, their use for medicinal purposes is being challenged by the development of resistance to these molecules by microorganisms and by cancer cells. Additionally, use of a particular polyketide for the treatment of a 60 patient can be inhibited by unwanted side effects caused by the molecule, or the failure of the molecule to have the desired level of activity. To combat these issues, new derivatives of polyketides are needed. One approach to generate new derivatives is to modify known polyketides through synthetic 65 or semisynthetic chemistry. While successful in many cases, the more complicated the polyketide structure, the less effi-

cient a synthetic or semisynthetic approach is. A complementary approach is to use metabolic engineering of the polyketide biosynthetic pathway to generate new structural derivatives. Although this approach has been successful in generating new polyketides, one of the restrictions in its use has been the limited number of precursors, or extender units, which can be incorporated into a polyketide backbone by the Type I PKSs.

The flexibility of Type I PKSs has been exploited for the generation of metabolically engineered "natural" products through combinatorial biosynthesis. One example is to replace a catalytic domain from one Type I PKS with an alternative domain from a different Type I PKS, resulting in a hybrid enzyme that generates a hybrid product. This approach was shown to generate a library of nearly 60 erythromycin derivatives by exchanging catalytic domains from the erythromycin Type I PKS with catalytic domains from the erythromycin Type I PKS (McDaniel et al., 1999, *Proc. Natl. Acad. Sci. USA* 96: 1846-1851). Thus, combinatorial biosynthesis complements the more traditional approaches of using total or semisynthetic chemistry to generate structural diversity.

Changing the extender unit(s) incorporated into a polyketide can be used to vary the moiety that extends away from the backbone of the polyketide, which can have effects on its interaction with its biological target. Changes available using this approach are limited because of the limited number of known Type I PKS extender units-only four: malonyl-CoA, methylmalonyl-CoA, ethylmalonyl-CoA, and methoxymalonyl (MM)-ACP (FIG. 2). These extender units result in the incorporation of acetyl, propionyl, butyryl, or methoxyacetyl moieties into the polyketide backbone, respectively. The chemical attributes of these extender units are similar, with the exception of the potential hydrogen bonding interactions by the oxygen of the methoxy moiety. However, for all of these extender units, the moieties on the α -carbons lack simple chemical reactivity for further downstream modification by semisynthetic chemistry. Due to these limitations, there is an interest in identifying or generating new extender units with different chemical attributes to enhance structural diversification by combinatorial biosynthesis and increase the opportunities for downstream modification by semisynthetic chemistry.

The inventors of the present patent application previously published a paper proposing the existence of previously unknown hydroxymalonyl-ACP (HM-ACP), and aminomalonyl-ACP (AM-ACP) extender units (Emmert et al., 2004, Appl. Environ. Microbiol. 70: 104-113). In that paper, the mechanism of AM-ACP formation was proposed and has been subsequently confirmed. Although Emmert et al. proposed a mechanism for HM-ACP formation, the proposed mechanism has since been determined to be incorrect. The precursor is not glycerate, a glyceryl-CoA intermediate is not formed, and Orf2 (ZmaF) does not play a role in HM-ACP formation. Emmert et al. further proposed the minimal biosynthetic machinery for zwittermicin A assembly involving the incorporation of AM-ACP and HM-ACP, shown in FIG. 4; however, the identity of the necessary acyltransferase (AT) domains for incorporation of these extender units was not disclosed. These AT domains are the essential components needed for AM-ACP and HM-ACP recognition and incorporation. At the time, there were many potential mechanisms for AM-ACP and HM-ACP incorporation, but it was not known which mechanism was correct. In accordance with the present invention, novel enzymes responsible for the biosynthesis of zwittermicin A have been discovered.

BRIEF SUMMARY

Methods and compositions for the synthesis of polyketide synthase (PKS) enzymes are provides. Also provided are methods and compositions for the synthesis of extender units incorporated into polyketide molecules.

Isolated polynucleotides encoding polypeptides comprising amino acid sequences selected from the group consisting of: a) an amino acid sequence of SEQ ID NO:1 (i.e., Zma N), 5 b) an amino acid sequence that is at least 90% identical to SEQ ID NO:1, and c) an amino acid sequence of a) or b) having 1 to 30 conservative amino acid substitutions, are provided. The polypeptides have phosphatase and acyltransferase activity. The polypeptides are involved in converting 10 1,3-bisphosphoglycerate to glyceryl-acyl carrier protein. Further provided are expression vectors that include the isolated polynucleotides. Also provided are host cells that include the expression vectors which comprise these polynucleotides. The above expression vectors may further include polynucle- 15 otides encoding polypeptides comprising the sequences of SEQ ID NO:2 (i.e., Zma D), SEQ ID NO:3 (i.e., Zma E), and SEQ ID NO:4 (i.e., Zma G). Provided are host cells that include these expression vectors. Alternatively, the expression vectors may include polynucleotides encoding polypep- 20 tides comprising sequences that are at least 90% identical to SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, and SEQ ID NO:4. One or more of the sequences that are at least 90% identical to SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3 and SEQ ID NO:4 may operably be connected to separate pro- 25 moters. Also provided are host cells that include these expression vectors.

Host cells are provided, which include polynucleotides encoding polypeptides comprising amino acid sequences selected from the group consisting of: a) an amino acid 30 sequence of SEQ ID NO:1 (i.e., Zma N), b) an amino acid sequence that is at least 90% identical to SEQ ID NO:1, and c) an amino acid sequence of a) or b) having 1 to 30 conservative amino acid substitutions where the polypeptides have phosphatase and acyltransferase activity. The host cells fur-35 ther include expression vectors that include polynucleotides encoding polypeptides comprising the amino acids sequences of SEQ ID NO:1, SEQ ID NO:2, SEQ ID NO:3, and SEQ ID NO:4. One or more of these polynucleotides may operably be connected to separate promoters. 40

Isolated polypeptides comprising amino acid sequences selected from the group consisting of: a) an amino acid sequence of SEQ ID NO:1 (i.e., Zma N), b) an amino acid sequence that is at least 90% identical to SEQ ID NO:1, and c) an amino acid sequence of a) or b) having 1 to 30 conser- 45 vative amino acid substitutions, are provided. The polypeptides have phosphatase and acyltransferase activity. Host cells comprising these polypeptides are also provided.

Methods are provided that include expressing, in host cells, expression vectors that comprise polynucleotides encoding 50 polypeptides comprising amino acid sequences selected from the group consisting of: a) an amino acid sequence of SEQ ID NO:1 (i.e., Zma N), b) an amino acid sequence that is at least 90% identical to SEQ ID NO:1, and c) an amino acid sequence of a) or b) having 1 to 30 conservative amino acid 55 substitutions, where the polypeptides have phosphatase and acyltransferase activity. In the practice of the methods, these expression vectors may express in the presence of 3-phosphoglyceric acid. The methods may further include expressing, in host cells, expression vectors that include polynucleotides 60 encoding polypeptides comprising sequences that are at least 90% identical to SEQ ID NO:2, SEQ ID NO:3, and SEQ ID NO:4. One or more of these polynucleotides may be located on separate expression vectors. As well, each of these polynucleotides may be located on a separate expression vector. 65

Alternatively, the methods of the present invention may include expressing, in host cells: 1) expression vectors that comprise polynucleotides encoding polypeptides comprising amino acid sequences selected from the group consisting of: a) an amino acid sequence of SEQ ID NO:1 (i.e., Zma N), b) an amino acid sequence that is at least 90% identical to SEQ ID NO:1, and c) an amino acid sequence of a) or b) having 1 to 30 conservative amino acid substitutions, where the polypeptides have phosphatase and acyltransferase activity, and 2) expression vectors that include polynucleotides encoding polypeptides having the amino acid sequences of SEQ ID NO:2, SEQ ID NO:3, and SEQ ID NO:4. One or more of these polynucleotides may be located on separate expression vectors. As well, each of these polynucleotides may be located on a separate expression vector.

Isolated polynucleotides are provided, which encode polypeptides comprising: a) an amino acid sequence of SEQ ID NO:7 (i.e., the KS1 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:7, or an amino acid sequence of SEQ ID NO:7 having 1-40 conservative amino acid substitutions, b) an amino acid sequence of SEO ID NO:8 (i.e., the KR1 domain of ZmaA), an amino acid sequence that is at least 90% identical to SEQ ID NO:8, or an amino acid sequence of SEQ ID NO:8 having 1-20 conservative amino acid substitutions, and c) an amino acid sequence of SEQ ID NO:9 (i.e., the ACP1 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:9, or an amino acid sequence of SEQ ID NO:9 having 1-6 conservative amino acid substitutions, where the polypeptides have the biological activity of recognition, activation, and condensation of AM-ACP into a polyketide backbone. The present invention also provides expression vectors comprising these polynucleotides. The present invention also provides host cells that include the expression vectors comprising these polynucleotides. The host cells may further include polynucleotides encoding polypeptides comprising the amino acid sequence of SEQ ID NO:6 (i.e., Zma F), an amino acid sequence that is at least 90% identical to SEQ ID NO:6, or an amino acid sequence of SEQ ID NO:6 having 1-40 conservative amino acid substitutions, where the polypeptides have the biological activity of catalyzing the 40 incorporation of ethanolamine subunits from AM-ACP into polyketides.

Isolated polynucleotides are provided, which encode polypeptides comprising the amino acid sequence of SEQ ID NO:5 (i.e., Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:5, or an amino acid sequence of SEQ ID NO:5 having 1-300 conservative amino acid substitutions, where the polypeptides have the biological activity of catalyzing the incorporation of an ethanolamine subunit from AM-ACP into a polyketide. Also provided are expression vectors that include these isolated polynucleotides. Host cells are provided that include these expression vectors. The host cells may further include expression vectors comprising polynucleotides that encode polypeptides comprising the amino acid sequence of SEQ ID NO:6 (i.e., Zma F), an amino acid sequence that is at least 90% identical to SEQ ID NO:6, or an amino acid sequence of SEQ ID NO:6 having 1-40 conservative amino acid substitutions, where the polypeptides have the biological activity of catalyzing the incorporation of an ethanolamine subunit from AM-ACP into a polyketide.

Isolated polynucleotides are provided, which encode polypeptides that include: a) an amino acid sequence of SEQ ID NO:10 (i.e., the KS2 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:10, or an amino acid sequence of SEQ ID NO:10 having 1-40 conservative amino acid substitutions, b) an amino acid sequence of SEQ ID NO:11 (i.e., the AT domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:11, or an amino acid sequence of SEQ ID NO:11 having 1-30 conservative amino acid substitutions, c) an amino acid sequence of SEQ ID NO:12 (i.e., the KR2 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:12, or an amino acid sequence of SEQ ID NO:12 having 1-20 conservative amino acid substitutions, and d) an amino acid sequence of SEQ ID NO:13 (i.e., the ACP2 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:13, or an amino acid sequence of SEQ ID NO:13 10 having 1-6 conservative amino acid substitutions. The polypeptides have the biological activity of recognition, activation, and condensation of glycolyl subunits from HM-ACP into polyketides. Further provided are expression vectors that include these polynucleotides. Also provided are host cell that 15 include these expression vectors.

Provided are isolated polynucleotides that encode polypeptides comprising the amino acid sequence of SEQ ID NO:5, an amino acid sequence that is at least 90% identical to SEQ ID NO:5, or an amino acid sequence of SEQ ID NO:5 20 having 1-300 conservative amino acid substitutions, where the polypeptides have the biological activity of catalyzing the incorporation of glycolyl subunits from HM-ACP into polyketides. Provided are expression vectors that comprise these polynucleotides. Also provided are host cells compris- 25 ing these expression vectors.

Methods for incorporating AM-ACP extender units into polyketide molecules are provided. The methods include reacting: 1) polypeptides comprising: a) an amino acid sequence of SEQ ID NO:7 (i.e., the KS1 domain of Zma A), 30 an amino acid sequence that is at least 90% identical to SEQ ID NO:7, or an amino acid sequence of SEQ ID NO:7 having 1-40 conservative amino acid substitutions, b) an amino acid sequence of SEQ ID NO:8 (i.e., the KR1 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ 35 ID NO:8, or an amino acid sequence of SEQ ID NO:8 having 1-20 conservative amino acid substitutions, and c) an amino acid sequence of SEQ ID NO:9 (i.e., the ACP1 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:9, or an amino acid sequence of SEQ ID NO:9 40 having 1-6 conservative amino acid substitutions, and 2) polypeptides comprising the amino acid sequence of SEQ ID NO:6 (i.e., Zma F), an amino acid sequence that is at least 90% identical to SEQ ID NO:6, or an amino acid sequence of SEQ ID NO:6 having 1-40 conservative amino acid substitu- 45 tions, with AM-ACP, where the polypeptides incorporate the AM-ACP extender units into the polyketide molecules. The methods may further include expressing polynucleotides that encode the above polypeptides in host cells. Alternatively, the methods for incorporating AM-ACP extender units into 50 polyketide molecules may include reacting: 1) polypeptides comprising the amino acid sequence of SEQ ID NO:6 (i.e., Zma F), an amino acid sequence that is at least 90% identical to SEQ ID NO:6, or an amino acid sequence of SEQ ID NO:6 having 1-40 conservative amino acid substitutions, and 2) 55 polypeptides comprising the amino acid sequence of SEQ ID NO:5, an amino acid sequence that is at least 90% identical to SEQ ID NO:5, or an amino acid sequence of SEQ ID NO:5 having 1-300 conservative amino acid substitutions, with AM-ACP, where the polypeptides incorporate the AM-ACP 60 extender unit into the polyketide molecules. The methods may further include expressing polynucleotides that encode the above polypeptides in host cells.

Methods for incorporating HM-ACP extender units into polyketide molecules are provided. The methods include 65 reacting polypeptides that comprise: a) an amino acid sequence of SEQ ID NO:10 (i.e., the KS2 domain of Zma A), 6

an amino acid sequence that is at least 90% identical to SEQ ID NO:10, oran amino acid sequence of SEQ ID NO:10 having 1-40 conservative amino acid substitutions, b) an amino acid sequence of SEQ ID NO:11 (i.e., the AT domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:11, or an amino acid sequence of SEQ ID NO:11 having 1-30 conservative amino acid substitutions, c) an amino acid sequence of SEQ ID NO:12 (i.e., the KR2 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:12, or an amino acid sequence of SEQ ID NO:12 having 1-20 conservative amino acid substitutions, and d) an amino acid sequence of SEQ ID NO:13 (i.e., the ACP2 domain of Zma A), an amino acid sequence that is at least 90% identical to SEQ ID NO:13, or an amino acid sequence of SEQ ID NO:13 having 1-6 conservative amino acid substitutions, with HM-ACP, where the polypeptides incorporate the HM-ACP extender units into polyketides. The methods may further include expressing polynucleotides that encode the above polypeptides in host cells.

Alternatively, the methods for incorporating HM-ACP extender units into polyketide molecules include reacting polypeptides comprising: a) the amino acid sequence of SEQ ID NO:5, b) an amino acid sequence that is at least 90% identical to SEQ ID NO:5, or c) an amino acid sequence of SEQ ID NO:5 having 1-300 conservative amino acid substitutions, with HM-ACP, where the polypeptides incorporate the HM-ACP extender units into polyketides. The methods may further include expressing polynucleotides that encode the above polypeptides in host cells.

Polyketide molecules that include one or more noncognate glycolyl subunits are provided; these polyketide molecules may be modified erythromycin PKSs. Also provided are polyketide molecules that include one or more noncognate ethanolamine subunits; these polyketide molecules may be modified erythromycin PKSs.

Host cells comprising heterologous polyketide molecules comprising one or more noncognate glycolyl subunits are provided. Also provided are host cells that include heterologous polyketide molecules comprising one or more noncognate ethanolamine subunits.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows the chemical structures of representative natural products synthesized wholly or in part by Type I PKSs.

FIG. **2** illustrates the chemical structures of known Type I PKS extender units.

FIG. **3** illustrates the chemical structures of two novel Type I polyketide synthase extender units of this invention, hydroxymalonyl-ACP (HM-ACP), and aminomalonyl-ACP (AM-ACP).

FIG. **4** is a schematic representation of the HM-ACP biosynthetic pathway (top) and the AM-ACP biosynthetic pathway (bottom) used by *Bacillus cereus* for zwittermicin A (ZMA) production.

FIG. **5** illustrates possible pathways for ACP-linked PKS extender units.

FIG. 6 is a graph showing HPLC analysis of ZmaD.

FIG. 7 shows ESI-FT-ICR-MS spectra of the intermediates in HM-ZmaD formation.

FIG. 8 is a graph showing HPLC analysis of ZmaH.

FIG. **9** shows ESI-FT-ICR-MS spectra of the intermediates in AM-ZmaH formation.

FIG. **10** is an image showing analysis of purified proteins by SDS-PAGE (12%) followed by Coomassie blue staining.

FIG. 11 shows ESI-FT-ICR-MS spectra of AM-ZmaH reactions

FIG. 12 is a schematic representation of the portion of the ZMA nonribosomal peptide synthetase (NRPS) and a Type I PKS that can be generated according to this invention.

FIG. 13 is a schematic representation of wild-type DEBS1-Te and its derivatives that can be generated according to this invention.

FIG. 14 is a schematic representation of the chemical structures of erythromycin (center) and putative six erythromycin 10 derivatives that can be generated according to this invention.

DETAILED DESCRIPTION OF THE DRAWINGS AND THE PRESENTLY PREFERRED **EMBODIMENTS**

Generally, the nomenclature and the laboratory procedures in recombinant DNA technology described below are those well known and commonly employed in the art. Standard techniques are used for cloning, DNA and RNA isolation, 20 or a modular polyketide synthase refers to sufficient portions amplification and purification. Generally enzymatic reactions involving DNA ligase, DNA polymerase, restriction endonucleases and the like are performed according to the manufacturer's specifications. These techniques and various other organic chemistry techniques are generally performed 25 according to Sambrook et al., 1989, Molecular Cloning-Laboratory Manual, Cold Spring Harbor Laboratory, Cold Spring Harbor, N.Y.; Ausubel et al., 1993, Current Protocols in Molecular Biology, Volumes 1-3, John Wiley & Sons, Inc.; Kriegler, 1990, Gene Transfer and Expression: A Laboratory 30 Manual, Stockton Press, New York; Overman, 2005, Organic Reactions, Wiley; and March, 1992, Advanced Organic Chemistry: Reactions, Mechanisms and Structure, 4th Ed., Wiley-Interscience, New York, each of which is incorporated herein by reference in its entirety.

The term "isolated polynucleotide," as used herein, means a polynucleotide of genomic, cDNA, or synthetic origin or some combination thereof, which by virtue of its origin (1) is not associated with all or a portion of a polynucleotide in which the isolated polynucleotide is found in nature, (2) is 40 linked to a polynucleotide to which it is not linked in nature, or (3) does not occur in nature as part of a larger sequence. The term "isolated protein" or "isolated polypeptide," as used herein, means that a subject protein (1) is free of at least some other proteins with which it would typically be found in 45 nature, (2) is essentially free of other proteins from the same source, e.g., from the same species, (3) is expressed by a cell from a different species, (4) has been separated from at least about 50 percent of polynucleotides, lipids, carbohydrates, or other materials with which it is associated in nature, (5) is not 50 associated (by covalent or noncovalent interaction) with portions of a protein with which the "isolated protein" is associated in nature, (6) is operably associated (by covalent or noncovalent interaction) with a polypeptide with which it is not associated in nature, or (7) does not occur in nature. Such 55 an isolated protein can be encoded by genomic DNA, cDNA, mRNA or other RNA, of synthetic origin, or any combination thereof. Preferably, the isolated protein is substantially free from proteins or polypeptides or other contaminants that are found in its natural environment that would interfere with its 60 need not be the native genes, but can be mutants or analogs use (therapeutic, diagnostic, prophylactic, research or otherwise). Alternatively, the isolated protein is sufficiently free from proteins or polypeptides or other contaminants that are found in its natural environment that the isolated protein is capable of being used (for therapeutic, diagnostic, prophylac- 65 tic, research or other applications) in a manner that it could not be used in its natural environment.

8

In general, a polypeptide homolog includes any homolog in which residues at a particular position in the sequence have been substituted by other amino acids, and further includes the possibility of inserting an additional residue or residues between two residues of the parent protein as well as the possibility of deleting one or more residues from the parent sequence. Any amino acid substitution, insertion, or deletion is encompassed by the invention. In some embodiments, the amino acid substitution is a conservative substitution. Conservative substitutions whereby an amino acid of one class is replaced with another amino acid of the same type fall within the scope of the invention so long as the substitution does not materially alter the biological activity of the compound. For example, a homolog of SEQ ID NO:1 shares the same amino 15 acid sequence as SEQ ID NO:1 except for a few amino acid differences, e.g., substitutions, insertions, or deletions. When expressed in vitro, both SEQ ID NO:1 and its homolog are expected to exhibit essentially similar function.

A single "module" of a modular PKS extender gene cluster of the extender gene cluster to encode, or sufficient portions of the polyketide synthase to include, at least the activities required to effect the condensation of a single extender unit onto a starter unit or a growing polyketide chain. At least one module for the effective synthesis of a polyketide must contain an additional AT and ACP in order to effect the initial condensation. In addition, and optionally, the module may include a ketoreductase activity (KR), a cyclase, a dehydratase (DH), an enoyl reductase (ER), and/or a thioesterase (TE).

In native forms of aromatic polyketide synthases, portions of the required activities may occur on different proteins. In the case of aromatic polyketide synthases, a ketosynthase (KS), an acyl transferase (AT) and an acyl carrier protein (ACP) must be present to effect the condensation of a single extender unit onto a starter unit or a growing polyketide. Various activities associated with reduction, cyclization, aromatization and further derivatization may also be present. There must also be at least one chain-length limiting factor (CLF).

The phrases "PKS extender gene cluster", "PKS extender unit gene cluster" and "PKS extender gene set" are used interchangeably to mean any set of PKS genes capable of producing a PKS extender unit that forms a precursor that feeds into a PKS to generate a polyketide when under the direction of one or more compatible control elements in a host cell. A functional PKS is one which catalyzes the condensation of at least one extender unit onto a growing polyketide, i.e., has at least one functional module, or extension function either in vivo or in vitro. A "PKS extender gene cluster" thus need not include all of the genes found in the corresponding cluster in nature. Furthermore, the cluster can include PKS extender unit genes derived from a single species, or may be hybrid in nature with, e.g., a coding sequence derived from a cluster for the synthesis of a particular polyketide replaced with a corresponding coding sequence from a cluster for the synthesis of another polyketide. Hybrid clusters can include genes derived from either or both modular and aromatic PKSs. The genes included in the extender unit gene cluster thereof. Mutants or analogs may be prepared by the deletion, insertion or substitution of one or more nucleotides of the coding sequence, by site-directed mutagenesis, or other techniques known in the art.

A "PKS extender gene cluster" may also contain genes coding for modifications to the core polyketide produced by the PKS, including, for example, genes encoding postpolyketide synthesis enzymes derived from natural products pathways such as O-methyltransferases and glycosyltransferases. A "PKS extender gene cluster" may further include genes encoding hydroxylases, methylases or other alkylases, oxidases, reductases, glycotransferases, lyases, ester or 5 amide syntheses, and various hydrolases such as esterases and amidases. The genes included in the PKS extender gene cluster need not be on the same plasmid or, if present on the same plasmid, can be controlled by the same or different control sequences.

The cloning, analysis, and recombinant DNA technology of genes that encode PKS enzymes allow one to manipulate a known PKS extender gene cluster either to produce the polyketide synthesized by that PKS at higher levels than occur in nature or in hosts that otherwise do not produce the 15 polyketide. The technology also allows one to produce molecules that are structurally related to, but distinct from, the polyketides produced from known PKS extender gene clusters; see, e.g., PCT publication Nos. WO 93/13663; 95/08548; 96/40968; 97/02358; 98/27203; and 98/49315; 20 U.S. Pat. Nos. 4,874,748; 5,063,155; 5,098,837; 5,149,639; 5,672,491; 5,712,146; 5,830,750; 5,843,718; 6,274,560; 6,531,299; 6,551,802; 6,660,862; 6,750,040; 6,753,173; 6,939,691; and 7,101,684; Fu et al., 1994, Biochemistry 33: 9321-9326; McDaniel et al., 1993, Science 262: 1546-550; 25 Rohr, 1995, Angew. Chem. Int. Ed. Engl. 34: 881-888, each of which is incorporated herein by reference.

A "host cell" is a cell and the progeny and cultures thereof derived from a prokaryotic microorganism or a eukaryotic cell line cultured as a unicellular entity, which can be, or has 30 been, used as a recipient for recombinant vectors bearing the PKS extender gene clusters of the invention. It is understood that the progeny of a single parental cell may not necessarily be completely identical in morphology or in genomic or total DNA complement to the original parent, due to accidental or 35 deliberate mutation. Progeny of the parental cell which are sufficiently similar to the parent to be characterized by the relevant property, such as the presence of a nucleotide sequence encoding a desired PKS, are included in the definition, and are covered by the above terms. A "host cell" is a 40 naturally occurring cell or a transformed cell that contains an isolated expression vector and supports the replication or expression of the expression vector. Host cells may be cultured cells, explants, cells in vivo, and the like. A host cell can be homologous with respect to the polypeptide that is 45 expressed using the isolated expression vector. Alternatively, a host cell can be heterologous with respect to the polypeptide that is expressed using the expression vector. Host cells may be prokaryotic cells such as E. Coli, or eukaryotic cells such as yeast, insect, amphibian, or mammalian cells such as CHO, 50 HeLa, and the like.

A "noncognate" molecule or subunit of a molecule is one that has been introduced by means of metabolic engineering and that does not exist in its native form. A noncognate subunit of a polyketide is a subunit that has been introduced 55 into a polyketide via genetic engineering, metabolic engineering, or both. For example, a PKS enzyme may be modified so that it incorporates the noncognate subunit into a polyketide molecule.

"Metabolic engineering" refers to genetic engineering that 60 is used to modify one or more metabolic pathways. For example, a PKS molecule can be genetically engineered to incorporate one or more noncognate subunits into a polyketide molecule, thereby synthesizing a metabolically engineered polyketide molecule. 65

A "functional homolog" or "functional equivalent" or "functional fragment" of a polypeptide of the present invention is a polypeptide that is homologous to the specified polypeptide but has one or more amino acid differences from the specified polypeptide. A functional fragment or equivalent of a polypeptide retains at least some, if not all, of the activity of the specified polypeptide.

In general, a PKS polypeptide functional homolog that preserves PKS polypeptide-like function includes any homolog in which residues at a particular position in the sequence have been substituted by other amino acids, and 10 further includes the possibility of inserting an additional residue or residues between two residues of the parent protein as well as the possibility of deleting one or more residues from the parent sequence. Any amino acid substitution, insertion, or deletion is encompassed by the invention. In some embodiments, the amino acid substitution is a conservative substitution. Conservative substitutions whereby an amino acid of one class is replaced with another amino acid of the same type fall within the scope of the invention so long as the substitution does not materially alter the biological activity of the compound. For example, a functional equivalent of SEO ID NO:1 shares the same amino acid sequence as SEQ ID NO:5 except for a few amino acid differences, e.g., substitutions, insertions, or deletions. When expressed in a cell, both SEQ ID NO:5 and its functional homolog are expected to catalyze incorporation of a glycolyl subunit into a polyketide.

A "coding sequence" or a sequence that "encodes" a protein or peptide is a nucleic acid sequence which is transcribed into mRNA (in the case of DNA) or translated into a polypeptide (in the case of mRNA) in vitro or in vivo when placed under the control of appropriate regulatory sequences.

"Control sequences" refers collectively to polynucleotide sequences that can affect expression (including transcription and translation), processing or intracellular localization of coding sequences to which they are ligated, such as, for example, promoter sequences, ribosome binding sites, polyadenylation signals, transcription termination sequences, upstream regulatory domains, enhancers, and the like. Not all of these control sequences need always be present in a recombinant vector so long as the desired gene is capable of being expressed and processed.

"Operably linked" means that the components to which the term is applied are in a relationship or configuration that allows them to carry out their usual functions under suitable conditions. Thus, control sequences operably linked to a coding sequence are capable of effecting the expression of the coding sequence. The control sequences need not be contiguous with the coding sequence, so long as they function to direct the expression thereof. Thus, for example, intervening untranslated yet transcribed sequences can be present between a promoter sequence and the coding sequence and the promoter sequence can still be considered "operably linked" to the coding sequence.

A "library" or "combinatorial library" of polyketides is intended to mean a collection of a multiplicity of different polyketides. The differences in the members of the library may result from their being produced by different PKS systems that contain any combination of native, homolog or mutant genes from aromatic, modular or fungal PKSs. The differences in the members of the library may also result from the use of different starter units, extender units and conditions. The PKSs in the systems used to generate the library may be derived from a single system, such as act, fren, gra, tcm, whie, gris, ery, or the like, and may optionally include genes encoding tailoring enzymes which are capable of catalyzing the further modification of a polyketide. Alternatively, the combination of synthase activities can be rationally or stochastically derived from an assortment of synthases, e.g., a synthase system can be constructed to contain the KS/AT component from an act PKS, the CLF component from a gra PKS and an ACP component from a fren PKS. The synthase can optionally include other enzymatic activities as well.

The term "incorporating," as used in the context of a PKS 5 enzyme "incorporating" an extender unit into a polyketide molecule, means that the PKS enzyme incorporates a subunit of the extender unit into the polyketide molecule. The PKS enzyme may incorporate a subunit of the extender unit into the polyketide molecule, for example, by condensation of the extender unit with a starter unit or with a previously incorporated extender unit. For example, a glycolyl subunit is incorporated into the polyketide molecule from the HM-ACP extender unit. As well, an ethanolamine subunit is incorporated into the polyketide molecule from the AM-ACP unit. 15 The incorporation of an HM-ACP extender unit into a polyketide molecule thus refers to the incorporation of a glycolyl subunit from the HM-ACP extender unit into the polyketide molecule. As well, the incorporation of an AM-ACP extender unit into a polyketide molecule thus refers to 20 coding for a homolog of an FkbH protein. The newly isolated the incorporation of an ethanolamine subunit from the AM-ACP extender unit into the polyketide molecule.

"Optional" or "optionally" means that the subsequently described event or circumstance may or may not occur, and that the description includes instances where said event or 25 circumstance occurs and instances where it does not. For example, the phrase "optionally further purified" means that further purification may or may not be performed and that the description includes both the performance and the lack of performance of such further purification.

As used in this specification and the appended claims, the singular forms "a," "an" and "the" include plural references unless the content clearly dictates otherwise. Thus, reference to "a polyketide synthase" includes mixtures of polyketide synthases; reference to "an extender unit" includes mixtures 35 of such extender units, and the like.

FIG. 1 shows structures of representative natural products synthesized wholly or in part by Type I PKSs. Bold carbons and bonds in the structures denote selected components derived from different extender units: (i) pikromycin, malo- 40 nyl-CoA and methylmalonyl-CoA; (ii) coronatine, ethylmalonyl-CoA; (iii) FK520, methoxymalonyl-acyl carrier protein (MM-ACP); and (iv) zwittermicin.

FIG. 2 illustrates the chemical structures of known Type I PKS extender units. The SH-CoA squiggle bond illustrates 45 coenzyme A; the SH-ACP squiggle bond illustrates 4'-phosphopantetheinvl-ACP. Two novel extender units for Type I polyketide synthases are provided: (1) hydroxymalonyl-acyl carrier protein (hydroxymalonyl-ACP; HM-ACP), and (2) aminomalonyl-acyl carrier protein (aminomalonyl-ACP, 50 AM-ACP (FIG. 3; see also Chan et al., 2006, Proc. Natl. Acad. Sci. U.S.A. 103: 14349-14354). These extender units have chemical attributes that are unique compared to those extender units that were previously known for the synthesis of polyketides. Provided herein is biochemical and mass spec- 55 tral evidence for the existence of two novel Type I PKS extender units, HM-ACP and AM-ACP. This is the first empirical evidence for the formation of ACP-linked Type I PKS extender units. Additionally, in one embodiment this invention provides that 1,3-bPG is the likely in vivo precursor 60 for the formation of HM-ACP and MM-ACP.

In one embodiment, this invention provides for the introduction of HM-ACP, AM-ACP extender units, or both, into a desired polyketide. Any one of these Type I polyketide synthase extender units may be incorporated into any polyketide 65 for the purpose of generating new structural derivatives. For example, these may be derivatives of medically or agricultur-

ally important polyketide-containing natural products. In one aspect, this invention provides the enzymes for achieving the introduction of HM-ACP and/or AM-ACP extender units into polyketides.

It is also possible to use the extender units of this invention for metabolic engineering of a portion of the erythromycin Type I PKS. The erythromycin Type I PKS can be engineered to incorporate HM-ACP or AM-ACP extender units. In one example of this invention, in vivo or in vitro erythromycin derivatives are produced, which incorporate HM-ACP and AM-ACP extender units into the polyketide backbone of this important antibiotic.

Provided also is the ability to introduce hydroxyl or amino group functionality into the polyketide backbone of a Type I polyketide-based product. Thus, in one aspect this invention expands the metabolic engineering potential of Type I PKSs, thereby introducing unprecedented structural diversity into the polyketide products, natural or synthetic.

In one embodiment, this invention provides a gene, zmaN, gene zmaN encodes a protein ZmaN. The amino acid sequence of ZmaN is shown as SEQ ID NO:1. This sequence has been deposited on Jun. 28, 2006 in the GenBank under accession number DQ830808. An identified function of zmaN is to convert 1,3-bisphosphoglycerate to glyceryl-acyl carrier protein. ZmaN functions as a phosphatase and acyltransferase, and is involved in hydroxymalonyl-acyl carrier protein formation.

The incorporation of AM-ACP and HM-ACP into a desired polyketide backbone requires not only the enzymology needed to form these unusual extender units, but also the enzymology for recognition, activation, and condensation of these extender units into the growing polyketide backbone. The enzymes that catalyze these steps are polyketide synthases (PKSs). The PKS that incorporates AM-ACP and HM-ACP is contained on two polypeptides, ZmaA (SEQ ID NO:5) and ZmaF (SEQ ID NO:6), obtained from Bacillus cereus. Thus, in one embodiment, this invention provides a gene, zmaA, coding for the protein ZmaA. The amino acid sequence of ZmaA is shown as SEQ ID NO:5. ZmaA is an eight-domain protein, which, in combination with ZmaF, is involved in the recognition, activation and condensation of AM-ACP into the polyketide backbone. The domains of the ZmaA protein are, in the following order: ketosynthase (KS1) (SEQ ID NO:7), consisting of amino acids 1-438; linker, consisting of amino acids 439-1001; ketoreductase (KR1) (SEO ID NO:8), consisting of amino acids 1002-1203; linker, consisting of amino acids 1204-1287; acyl carrier protein (ACP1) (SEQ ID NO:9), consisting of amino acids 1288-1352; linker, consisting of amino acids 1353-1374; ketosynthase (KS2) (SEQ ID NO:10), consisting of amino acids 1375-1800; linker, consisting of amino acids 1801-1897; acyltransferase (AT) (SEQ ID NO:11), consisting of amino acids 1898-2205; linker, consisting of amino acids 2206-2521; ketoreductase (KR2) (SEQ ID NO:12), consisting of amino acids 2522-2719; linker, consisting of amino acids 2720-2810; acyl carrier protein (ACP2) (SEQ ID NO:13), consisting of amino acids 2811-2875; linker, consisting of amino acids 2876-2891; condensation (C) domain, consisting of amino acids 2892-3336 (end). The linker domains are typically considered as being the sites of domain fusions. The linker domains are typically not drawn when representing PKS systems.

The following three domains are required for incorporation of AM-ACP into a polyketide: (i) ketosynthase (KS1), consisting of amino acids 1-438 (SEQ ID NO:7); (ii) ketoreductase (KR1) (SEQ ID NO:8), consisting of amino acids 1002-

1203; and (iii) acyl carrier protein (ACP1), consisting of amino acids 1288-1352 (SEQ ID NO:9). Incorporation of AM-ACP into a polyketide also requires the presence of ZmaF, in combination with the above KS1, KR1, and ACP1 domains of ZmaA.

ZmaA is involved in the recognition, activation, and condensation of HM-ACP into the polyketide backbone. The following four domains are required for incorporation of HM-ACP into a polyketide: (i) ketosynthase (KS2), consisting of amino acids 1375-1800 (SEQ ID NO:10); (ii) acyltransferase (AT), consisting of amino acids 1898-2205 (SEQ ID NO:11); (iii) ketoreductase (KR2), consisting of amino acids 2522-2719 (SEQ ID NO:12); and (iv) acyl carrier protein (ACP2), consisting of amino acids 2811-2875 (SEQ ID $_{15}$ NO:13).

ZmaF is an acyltransferase. The amino acid sequence of ZmaF is shown as SEQ ID NO:6.

ZmaA and ZmaF are unique in being the only known PKS for incorporation of AM-ACP and HM-ACP into polyketides. 20 The AT domains from ZmaF and ZmaA are unique and give insights into how to adjust a PKS system to incorporate AM-ACP or HM-ACP components.

In the case of recombinantly expressed polynucleotides of the present invention, the polynucleotides sequences can be 25 expresses using one expression vector. When one expression vector is used, one or more polynucleotide sequences can be expressed using one or more regulatory sequences, such as promoters. For example, one promoter can regulate the expression of one or more polynucleotide sequences. As well, 30 individual promoters can separately regulate the expression of polynucleotide sequences of the present invention. For example, if a vector includes three polynucleotide sequences, the expression of each of the three polynucleotide sequences can be independently regulated using a separate promoter. 35 The promoters can be identical. Alternatively, the promoters can be different, and, in the example above, the expression of each of the three polynucleotide sequences can be regulated by completely differing promoters. Combinations of these approaches can be used as well.

Alternatively, the sequences of the recombinantly expressed polynucleotides can be expressed using multiple expression vectors. Thus, for practicing the present invention, two or more vectors, where each vector expresses different nucleotides, can be designed. Each of these vectors can 45 express one or more polypeptides of the present invention. Each of these vectors can include one or more regulatory sequences, e.g. promoters, which are operably connected to the polynucleotide sequences of the present invention.

In the case of recombinantly expressed polypeptides, vari- 50 ous embodiments are contemplated. In some embodiments, the present invention contemplates recombinant expression of the entire sequences of the polypeptides of this invention, such as ZmaN, ZmaD, ZmaE, ZmaG, ZmaA, and ZmaF, or variations thereof. In other embodiments, the present inven- 55 tion contemplates recombinant expression of the amino acid sequences of individual domains of the polypeptides of the present invention, or variations thereof. For example, one or more expression vectors can be used to recombinantly express individually, or in any desirable groups, polynucle- 60 otide sequences encoding the amino acid domain sequences of ZmaA. Thus, in one embodiment, a skilled artisan can express each of the KS1, KR1, ACP1, KS2, AT, KR2, ACP2 domains of ZmaA individually, or in any desired combination. Such domains can be expressed from one expression 65 vector, or from multiple expression vectors. The same is also true for variants of these domains.

Host cells can be transformed or transfected using one or more expression vectors, which can express a variety of the polypeptides of this invention. Thus, a host cell can be engineered to express: (i) one or more of the ZmaF domains, or variants thereof; (ii) one or more polypeptides ZmaN, ZmaD, ZmaE, ZmaG, ZmaA, and ZmaF, or variations thereof; (iii) or any combinations thereof. To practice the methods of the present invention, it is also contemplated that one or more isolated polypeptides of the present invention can be introduced into a host cell, where the polypeptide(s) can react with other molecules, enzymes, and/or substrates.

In the case of recombinant polynucleotides of the present invention, the sequence of the recombinant polynucleotide need not be exactly identical to the corresponding isolated sequence. The introduced recombinant polynucleotide sequence will typically be substantially identical to the corresponding isolated sequence.

Two nucleic acid sequences or polypeptides are said to be "identical" if the sequence of nucleotides or amino acid residues in the two sequences is the same when aligned for maximum correspondence as described below. The term "complementary to" is used herein to mean that the sequence is complementary to all or a portion of a reference polynucleotide sequence.

Optimal alignment of sequences for comparison may be conducted by methods commonly known in the art, e.g., the local homology algorithm (Smith and Waterman, 1981, Adv. Appl. Math. 2:482-489), by the search for similarity method (Pearson and Lipman, 1988, Proc. Natl. Acad. Sci. USA. 85: 2444-2448), by computerized implementations of these algorithms (GAP, BESTFIT, BLAST, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Genetics Computer Group (GCG), Madison, Wis.), or by inspection. Protein and nucleic acid sequence identities may be evaluated using the Basic Local Alignment Search Tool ("BLAST") which is well known in the art (Karlin and Altschul, 1990, Proc. Natl. Acad. Sci. USA 87: 2267-2268; Altschul et al., 1997, Nucl. Acids Res. 25: 3389-3402) the disclosures of which are incorporated by reference in their entireties. The BLAST programs 40 identify homologous sequences by identifying similar segments, which are referred to herein as "high-scoring segment pairs," between a query amino or nucleic acid sequence and a test sequence which is preferably obtained from a protein or nucleic acid sequence database. The statistical significance of a high-scoring segment pair can be evaluated using the statistical significance formula (Karlin and Altschul, 1990), the disclosure of which is incorporated by reference in its entirety. The BLAST programs can be used with the default parameters or with modified parameters provided by the user.

"Percentage of sequence identity" is determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polynucleotide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. The percentage is calculated by determining the number of positions at which the identical nucleic acid base or amino acid residue occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison, and multiplying the result by 100 to yield the percentage of sequence identity.

The term "substantial identity" of polynucleotide sequences means that a polynucleotide comprises a sequence that has at least 25% sequence identity. Alternatively, percent identity can be any integer from 25% to 100%. More preferred embodiments include at least: 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98% or 99% identity compared to a reference sequence using the programs described herein; preferably BLAST using standard parameters, as described. One of skill will recognize that these values can be appropriately adjusted to determine corresponding identity of proteins encoded by two nucleotide sequences by taking into account codon degeneracy, amino acid similarity, reading frame positioning and the like.

Substantial identity of amino acid sequences for these purposes normally means sequence identity of at least 40%. Preferred percent identity of polypeptides can be any integer from 40% to 100%. More preferred embodiments include at least 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% identity compared to a reference sequence using the programs described herein; preferably BLAST using standard parameters, as described. 20 Polypeptides that are "substantially similar" share sequences as noted above except that residue positions which are not identical may differ by conservative amino acid changes.

Conservative amino acid substitutions refer to the interchangeability of residues having similar side chains and pref-25 erably have similar physical/chemical properties. For example, a group of amino acids having aliphatic side chains is glycine, alanine, valine, leucine, and isoleucine; a group of amino acids having aliphatic-hydroxyl side chains is serine and threonine; a group of amino acids having amide-contain- 30 ing side chains is asparagine and glutamine; a group of amino acids having aromatic side chains is phenylalanine, tyrosine, and tryptophan; a group of amino acids having basic side chains is lysine, arginine, and histidine; and a group of amino acids having sulfur-containing side chains is cysteine and 35 methionine. Preferred conservative amino acids substitution groups are: valine-leucine-isoleucine, phenylalanine-tyrosine, lysine-arginine, alanine-valine, aspartic acidglutamic acid, and asparagine-glutamine. Accordingly, polynucleotides of the present invention encoding a polypeptide 40 of the present invention include nucleic acid sequences that encode polypeptides with one or more conservative amino acid substitutions.

The number of conservative amino acid substitutions is any integer from 1 to 1000. For example, with respect to SEQ ID 45 NO:1, which has 359 amino acids, the number of conservative amino acid substitutions is 1 to 30 conservative amino acid substitutions, e.g. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, substitutions. In another example, with respect to SEQ ID NO:6, 50 which has 3336 amino acids, the number of conservative amino acid substitutions is 1 to 300 conservative amino acid substitutions, e.g. 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 35, 40, 45, 50, 60, 70, 80, 90, 100, 110, 120, 130, 140, 150, 160, 170, 55 180, 190, 200, 210, 220, 230, 240, 250, 260, 270, 280, 290, 300 substitutions. Polypeptides or proteins of the present invention thus include amino acid sequences that have substantial identity to the amino acid sequences of the present invention.

In one embodiment, the invention also relates to nucleic acids that selectively hybridize to the exemplified sequences, including hybridizing to the exact complements of these sequences. The specificity of single stranded DNA to hybridize complementary fragments is determined by the "stringency" of the reaction conditions. Hybridization stringency increases as the propensity to form DNA duplexes decreases.

In nucleic acid hybridization reactions, the stringency can be chosen to favor specific hybridizations (high stringency), which can be used to identify, for example, full-length clones from a library. Less-specific hybridizations (low stringency) can be used to identify related, but not exact, DNA molecules (homologous, but not identical) or DNA segments.

DNA duplexes are stabilized by: (1) the number of complementary base pairs, (2) the type of base pairs, (3) salt concentration (ionic strength) of the reaction mixture, (4) the temperature of the reaction, and (5) the presence of certain organic solvents, such as formamide, which decreases DNA duplex stability. In general, the longer the probe, the higher the temperature required for proper annealing. A common approach is to vary the temperature: higher relative temperatures result in more stringent reaction conditions. Ausubel et al. (1993) provide an excellent explanation of the stringency of hybridization reactions.

To hybridize under "stringent conditions" describes hybridization protocols in which nucleotide sequences at least 60% homologous to each other remain hybridized. Generally, stringent conditions are selected to be about 5° C. lower than the thermal melting point (Tm) for the specific sequence at a defined ionic strength and pH. The Tm is the temperature (under defined ionic strength, pH and nucleic acid concentration) at which 50% of the probes complementary to the target sequence hybridize to the target sequence at equilibrium. Since the target sequences are generally present at excess, at Tm, 50% of the probes are occupied at equilibrium.

"Stringent hybridization conditions" are conditions that enable a probe, primer or oligonucleotide to hybridize only to its target sequence. Stringent conditions are sequence-dependent and will differ. Stringent conditions comprise: (1) low ionic strength and high temperature washes (e.g. 15 mM sodium chloride, 1.5 mM sodium citrate, 0.1% sodium dodecyl sulfate at 50° C.); (2) a denaturing agent during hybridization (e.g. 50% (v/v) formamide, 0.1% bovine serum albumin, 0.1% Ficoll, 0.1% polyvinylpyrrolidone, 50 mM sodium phosphate buffer (pH 6.5; 750 mM sodium chloride, 75 mM sodium citrate at 42° C.); or (3) 50% formamide. Washes typically also comprise 5×SSC (0.75 M NaCl, 75 mM sodium citrate), 50 mM sodium phosphate (pH 6.8), 0.1% sodium pyrophosphate, 5×Denhardt's solution, sonicated salmon sperm DNA (50 µg/ml), 0.1% SDS, and 10% dextran sulfate at 42° C., with washes at 42° C. in 0.2×SSC (sodium chloride/ sodium citrate) and 50% formamide at 55° C., followed by a high-stringency wash consisting of 0.1×SSC containing EDTA at 55° C. Preferably, the conditions are such that sequences at least about 65%, 70%, 75%, 85%, 90%, 95%, 98%, or 99% homologous to each other typically remain hybridized to each other. These conditions are presented as examples and are not meant to be limiting.

"Moderately stringent conditions" use washing solutions and hybridization conditions that are less stringent (Sambrook et al, 1989), such that a polynucleotide will hybridize to the entire, fragments, derivatives, or analogs of that polynucleotide. One example comprises hybridization in 6×SSC, 5×Denhardt's solution, 0.5% SDS and 100 mg/ml denatured salmon sperm DNA at 55° C., followed by one or more
washes in 1×SSC, 0.1% SDS at 37° C. The temperature, ionic strength, and other conditions can be adjusted to accommodate experimental factors such as probe length. Other moderate stringency conditions have been described (Ausubel et al., 1993; Kriegler, 1990).

"Low stringent conditions" use washing solutions and hybridization conditions that are less stringent than those for moderate stringency (Sambrook et al., 1989), such that a polynucleotide will hybridize to the entire, fragments, derivatives, or analogs of that polynucleotide. A non-limiting example of low stringency hybridization conditions includes hybridization in 35% formamide, 5xSSC, 50 mM Tris HCl (pH 7.5), 5 mM EDTA, 0.02% PVP, 0.02% Ficoll, 0.2% BSA, 5 100 mg/ml denatured salmon sperm DNA, 10% (wt/vol) dextran sulfate at 40° C., followed by one or more washes in 2xSSC, 25 mM Tris HCl (pH 7.4), 5 mM EDTA, and 0.1% SDS at 50° C. Other conditions of low stringency, such as those for cross species hybridizations are well-described 10 (Ausubel et al., 1993; Kriegler, 1990).

The extender units of this invention can be used for combinatorial biosynthesis of Type I polyketide synthases (PKSs). Thus, in one example, this invention provides a method for the generation of new structural derivatives of 15 polyketide-containing natural products. Changing one or more of the extender units incorporated into a polyketide backbone can alter the structure and activity of a natural product such as a polyketide. The polyketide products may be further modified, typically by hydroxylation, oxidation and/ 20 or glycosylation, in order to exhibit desired functionality, e.g. antibiotic activity. Methods for glycosylating polyketides are generally known in the art; the glycosylation may be effected intracellularly by providing the appropriate glycosylation enzymes or may be effected in vitro using chemical synthetic 25 means.

The two novel extender units of the present invention are utilized by *Bacillus cereus* for the biosynthesis of zwittermicin A (ZMA). Thus, in one example of the present invention, these extender units can be used for in vitro biosynthesis of 30 zwittermicin A.

These extender units are of significant interest because they introduce unique hydrogen-bonding characteristics and chemical reactivity to the moiety tethered to the C2 of the extender unit. These extender units offer unique possibilities 35 for combinatorial biosynthesis and semisynthetic chemistry due to the introduction of free hydroxyl and amino moieties into a polyketide structure. Harnessing the biosynthetic potential of these two Type I PKS extender units substantially increases the ability to introduce new structural diversity into 40 polyketides.

Biochemical and mass spectral evidence for the formation of these extender units is also provided. This is the first direct evidence for the formation of ACP-linked extender units for polyketide synthesis. Interestingly, aminomalonyl-ACP for-45 mation involves enzymology typically found in nonribosomal peptide synthesis. The AM-ACP pathway uses NRPS enzymology (an adenylation and carrier protein pair) for the formation of a Type I PKS extender unit. Thus, AM-ACP can function as an NRPS extender unit in other enzyme systems. 50 For example, the antibiotic GE23077 is a cyclic nonribosomal peptide that contains an aminomalonate residue. Therefore, AM-ACP has the potential to function as a Type I PKS or an NRPS extender unit.

In one embodiment, this invention provides for metabolic 55 engineering of rifamycin production using the extender units of this invention. Rifamycin is an essential first-line drug against *M. tuberculosis* infections and new derivatives of this PKS-synthesized antibiotic are needed.

In another embodiment, this invention provides for metabolic engineering of Type I PKSs by changing the extender unit incorporated by a particular Type I PKS module. This approach involves replacing the catalytic domain that controls extender unit recognition and incorporation by a particular PKS module with the corresponding catalytic domain that recognizes a different extender unit. This domain is called the acyltransferase (AT) domain. Thus, to introduce an alterna-

tive PKS extender unit into a target Type I PKS, an AT domain that recognizes and incorporates the alternative extender unit must be identified. Type I PKS involved in ZMA biosynthesis may contain AT domains that recognize and incorporate HM-ACP and AM-ACP extender units (FIG. 7). To harness this metabolic engineering potential, the portability of these domains can be used into alternative Type I PKSs to generate novel hybrid molecules.

FIG. 7 shows ESI-FT-ICR-MS spectra of the intermediates in HM-ZmaD formation. The top of FIG. 7 depicts ZmaD intermediates of interest (from left to right: apo-, holo-[+340 Da], glycolyl-[+398 Da], glyceryl-[+428 Da], and HM-ZmaD [+442 Da]) and alignment to the representative peaks in the mass spectra as indicated by vertical dashed lines. Shown are the loading and corresponding mass shifts (1015-1070 m/z, +12 ions converted to mass scale) of (A) apo-ZmaD; (B) holo-ZmaD; (C) glyceryl-ZmaD; (D) HM-ZmaD; asterisks indicate signals arising from artifactual adduction: sodium (+22 Da), potassium (+38 Da), phosphate (+98 Da), and oxidation of Met/Cys residues (+16 Da). Insets show mass spectra and structures of 4'-Ppant (phosphopantetheinyl) elimination product.

It is to be understood that this invention is not limited to the particular methodology, protocols, subjects, or reagents described, and as such may vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to limit the scope of the present invention, which is limited only by the claims. The following examples are offered to illustrate, but not to limit the claimed invention.

EXAMPLES

Cloning of Biosynthetic Genes

Standard PCR-based cloning was used to introduce zmaD, zmaE, zmaG, zmaH, zmaI, zmaJ, and zmaN into the *Escherichia coli* overexpression vector pET28b (Novagen, Madison, Wis.). All expression vector clones result in the production of a protein with an N-terminal histidine tag. All clones were verified by sequencing at the University of Wisconsin Biotechnology Sequencing Center.

Heterologous Overproduction of Proteins

All expression constructs were introduced into *E. coli* BL21 (λ DE3). For overproduction of ZmaD, ZmaG, ZmaH, ZmaJ, and ZmaN, cells were grown at 25° C. in LB medium containing 50 µg/ml of kanamycin. At an OD₆₀₀ of 0.4-0.6, the temperature was reduced to 15° C., and cells were grown for 1.5-2.5 hours. Isopropyl-D-thiogalactopyranoside (IPTG) was then added to 60 µM, and the cells were grown an additional 16 hours at 15° C. For overproduction of ZmaE and ZmaI, cells were grown at 25° C. for 24 hours in LB medium containing 50 µg/ml of kanamycin without IPTG addition. Cells were harvested by centrifugation.

Purification of Proteins

Cells were resuspended in histidine-tag purification buffer (20 mM Tris pH 8, 300 mM NaCl, 10% [v/v] glycerol; for ZmaG: 20 mM Tris pH 8, 300 mM NaCl, 10% [w/v] sucrose). Cells were broken by sonication, and cell debris was removed by centrifugation. Imidazole was added to the cell-free extract to 5 mM, and the mixture was incubated with 1-2 ml of Ni-NTA agarose resin (Qiagen, Valencia, Calif.) for 1-2 hours at 4° C. with gentle rocking. The resin was collected by centrifugation and loaded into a column. The resin was washed with histidine-tag buffer containing 5 mM imidazole,

and stepwise elutions were performed with buffer containing increasing imidazole concentrations (20, 40, 60, 100, 250 mM).

Fractions containing purified protein based on SDS-PAGE/ Coomassie blue staining were pooled and dialyzed at 4° C. in 5 dialysis buffer (50 mM Tris pH 8, 100 mM NaCl, and 10% [v/v] glycerol; for ZmaG: 50 mM Tris pH 8, 100 mM NaCl, and 10% [w/v] sucrose; for ZmaI: 50 mM Tris pH 8, 300 mM NaCl, and 10% [v/v] glycerol). ZmaE was dialyzed further in high salt buffer (50 mM Tris pH 8, 300 mM NaCl, and 10% 10 [v/v] glycerol) and ZmaI was dialyzed in high salt buffer containing 100 µM FAD for 5 hours and then in high salt buffer lacking FAD. All proteins were concentrated, flash frozen with liquid nitrogen, and stored at -80° C. Protein concentrations were determined by the calculated molar 15 extinction coefficients (ZmaD, 2,560 M⁻¹ cm⁻¹; ZmaE, 44,410 M⁻¹ cm⁻¹; ZmaG, 21,180 M⁻¹ cm⁻¹; ZmaH, 2,560 $M^{-1} cm^{-1}$; ZmaI, 44,770 $M^{-1} cm^{-1}$; ZmaJ, 46760 $M^{-1} cm^{-1}$; ZmaN, 41,070 M^{-1} cm⁻¹).

Phosphopantetheinylation of ZmaD and ZmaH

Sfp from *Bacillus subtilis* was used for apo- to holo-ACP conversion as previously described (Quadri et al., 1998, *Bio-chemistry* 37: 1585-1595). Each reaction mixture contained 12.5 μ M apo-ACP, 75 mM Tris pH 7.5, 10 mM MgCl₂, 1 mM tris(2-carboxyethylphosphine) (TCEP), 50 or 500 μ M CoA, 25 and 1 μ M Sfp, and was incubated at 22° C. for 1 hour. Formation of Glyceryl-ZmaD

Reactions with 3-PG (130 or 260 μ l) contained: 10 μ M holo-ZmaD, 58 mM Tris pH 7.5, 8 mM MgCl₂, 0.8 mM TCEP, 385 μ M CoA, 0.8 μ M Sfp, 250 μ M D(–)₃—PG 30 (Sigma, St. Louis, Mo.), 5 mM ATP, and 1 μ M ZmaN, and were run for 40 min at 22° C. Control reactions were run without ZmaN, ATP, or with 2 U of 3-PGPK (Sigma). A time course comparing reactions with and without 3-PGPK contained 50 μ M 3-PG, and the reactions were run for 0.5, 2.0, 35 5.0, and 10 min.

Reactions containing glyceraldehyde-3-phosphate (150 μ l final volume) contained: 12.5 μ M holo-ZmaD, 75 mM Tris pH 7.5, 10 mM MgCl₂, 1 mM TCEP, 100 mM NaCl, 500 μ M CoA, 1 μ M Sfp, 250 μ M DL-glyceraldehyde-3-phosphate 40 (Sigma), 1 U GAPDH (Sigma), and 1 μ M ZmaN were run for 40 min at 22° C. Control reactions without GAPDH, DL-glyceraldehyde-3-phosphate, Sfp, or ZmaN were run, as well as control reactions in which holo-ZmaH replaced holo-ZmaD.

Formation of Seryl-ZmaH

Reaction mixtures (130 or 260 μ l) contained: 10 μ M holo-ZmaH, 58 mM Tris pH 7.5, 8 mM MgCl₂, 0.8 mM TCEP, 385 μ M CoA, 0.8 μ M Sfp, 250 μ M L-serine, 5 mM ATP, and 1 μ M ZmaJ. The reaction mixtures were incubated at 22° C. for 1 50 hour. To test whether seryl-ZmaD could be formed, 10 μ M holo-ZmaD replaced the 10 μ M holo-ZmaH in a 130 μ L reaction mixture.

Formation of AM-ZmaH

Reaction mixtures (130 or 260 μ L) contained the following 55 components: 10 μ M ZmaD, 58 mM Tris pH 7.5, 8 mM MgCl₂, 0.8 mM TCEP, 385 μ M CoA, 0.8 μ M Sfp, 250 μ M L-serine, 5 mM ATP, 1 μ M ZmaJ, 1 μ M ZmaG, 200 μ M NAD⁺, 1 μ M Zmal, and 100 μ M FAD. The reaction mixtures were run for 5 or 40 min at 22° C. Reactions were repeated 60 without ZmaG, Zmal, or replacing Zmal with 1 μ M ZmaE. High-Performance Liquid Chromatography (HPLC) Analysis of ZmaD and ZmaH Reaction Products

HPLC analysis of enzymatic reaction products was performed with a Vydac C18 peptide column (250×4.6 mm; 65 Grace Vydac, Deerfield, Ill.). In this experiment, 100-200 µl of apo- or holo-ZmaD or 130-200 µl of acylated ZmaD reac-

tions were injected, and products were separated using a 20-80% acetonitrile, 0.1% TFA gradient over 20 min at a flow rate of 1 ml/min; elution was monitored at A220. In this experiment, 100-200 μ l of apo- or holo-ZmaH or 130-200 μ l of aminoacylated ZmaH reaction products was injected, and products were separated using the same method as above.

Matrix-Assisted Laser Desorption Time-of-Flight Mass Spectrometry (MALDI-TOF MS) Analysis of ZmaD and ZmaH Reaction Products

The enzymatic reaction products were collected as they eluted from the HPLC, flash frozen with $CO_2(s)$ /ethanol (95%), and lyophilized overnight. Lyophilized samples were resuspended in ddH₂O and added to 1 µL of the sinipinic acid matrix (10 mg/ml in 50% acetonitrile, 0.05% TFA). MALDI-TOF MS analysis was performed using a VoyagerTM BiospectrometryTM Workstation (DE Pro) in linear mode (Applied Biosystems, Foster City, Calif.). Calibration was performed using apomyoglobin, bovine insulin, and cytochrome C (Sigma).

20 ATP-PPi Exchange Assays for ZmaJ

ZmaJ used in these assays was purified by an additional anion exchange chromatography step, which had no effect on seryl-ZmaH formation. ATP-PPi exchange assays were performed as previously described (Thomas et al., 2002, *Chem. Biol.* 9: 171-184). Reactions for amino acid specificity contained 70 nM ZmaJ and 1 mM of the following amino acids: L-Ser, L-2,3-diaminopropionate, L-Thr, Gly, and L-Cys. To determine the kinetic parameters of ZmaJ activation of L-Ser, 100 μ L reactions containing 70 nM ZmaJ, 3.5 mM ATP, and varying concentrations of L-Ser (0.35 to 10 mM), in triplicate, were incubated for 10 min prior to stopping the reactions. The reactions were in the linear range for enzyme concentration and less than 10% substrate-to-product conversion.

Analysis of Samples by Electrospray Ionization-Fourier Transform Ion Cyclotron Resonance Mass Spectrometry (ESI-FT-ICR-MS)

Mass analysis was performed on a custom-built 8.5 T Quadrupole-enhanced Fourier Transform Ion Cyclotron Resonance Mass Spectrometer (Q-FTMS) of the Marshall design. In general, a sample of interest was introduced to the mass spectrometer using a NanoMate 100 for automated nanospray (Advion Biosciences, Ithaca, N.Y.). Targeted species were externally accumulated in an octopole ion trap and either transferred to the ion cyclotron resonance (ICR) cell, isolated by Stored Waveform Inverse Fourier Transform (SWIFT), and fragmented by Infrared Multiphoton Dissociation (IRMPD) or fragmented in the trap (OCAD) and then transferred to the ICR cell for mass measurement. Collected data were analyzed using THRASH and/or manually interpreted, producing sets of intact mass data and fragment ion peak lists, which were uploaded onto the ProSightPTM (Taylor et al., 2003, Anal. Chem. 75: 4081-4086) web server for analysis in single protein mode. The protocol for 4'-Ppant elimination is described in (Dorrestein et al., 2006, Biochemistry 45: 12756-12766). All ESI-FT-ICR-MS experiments for glyceryl-ZmaD and HM-ZmaD used 3-PG as the starting substrate. **Bioinformatics Analysis and Protein Purification**

A set of five proteins is predicted to be involved in the formation of MM-ACP, an extender unit needed for the biosynthesis of FK520 (Wu et al., 2000, *Gene* 251: 81-90) (FIGS. 1B, 5A). This proposal is based on bioinformatics analysis of the FK520 biosynthetic gene cluster as well as biosynthetic gene clusters for other methoxyacetyl-containing natural products.

FIG. 5 illustrates proposed pathways for ACP-linked PKS extender units. FIG. 5A illustrates MM-ACP formation dur-

Formation of HM-ACP

ing FK520 biosynthesis. FIG. 5B illustrates HM-ACP formation during ZMA biosynthesis. FIG. 5C illustrates AM-ACP formation during ZMA biosynthesis. The squiggles in the chemical structures shown in FIG. 5 denote the 4'-Ppant prosthetic groups of the ACPs. For correlating previous Orf names (Emmert et al., 2004, Appl. Environ. Microbiol. 70: 104-113) to those shown above, the nomenclature is: ZmaD, Orf3; ZmaE, Orf1; ZmaG, Orf4; ZmaH, Orf5; ZmaI, Orf6; ZmaJ, Orf7.

The proposed MM-ACP pathway is as follows (using 10 FK520 protein nomenclature) (FIG. 5A): 1) FkbH binds to a glycolytic intermediate and dephosphorylates it while tethering it to an ACP, FkbJ, forming glyceryl-ACP; 2) FkbK catalyzes the oxidation of the glyceryl-ACP to 2-hydroxy-3-oxopropionyl-ACP (or 2,3,3-trihydroxypropionyl-ACP); 3) FkbI 15 converts the FkbK product to HM-ACP; and 4) FkbG catalyzes the O-methylation to form MM-ACP. During ansamitosin biosynthesis O-methylation occurs prior to incorporation by the PKS, therefore MM-ACP is the in vivo extender unit, and not HM-ACP (Carroll et al., 2002, J. Am. Chem. Soc. 20 124: 4176-4177). While genetic experiments support the hypothesis that these enzymes are involved in the incorporation of a MM-ACP extender unit, and a crystal structure of FkbI has been determined, biochemical evidence for MM-ACP has yet to be provided.

A part of the ZMA biosynthetic pathway was analyzed, and five genes were identified, which were coding for homologs of the MM-ACP pathway from FK520 (Emmert et al., 2004, Appl. Environ. Microbiol. 70: 104-113). Through sequencing of the ZMA biosynthetic gene cluster a gene, zmaN, coding 30 for a homolog of FkbH, was identified. Thus, the ZMA biosynthetic gene cluster codes for one homolog of both FkbH and FkbK, and two homologs of FkbJ and FkbI. An FkbG homolog is not coded within the biosynthetic gene cluster. The presence of two homologs of the ACP that is proposed to 35 carry the methoxymalonyl moiety for the MM-ACP extender unit points to the existence of two ACP-linked Type I PKS extender units for ZMA production.

One of these extender units, HM-ACP, can be generated in a similar manner to that proposed for MM-ACP, but lack of an 40 FkbG homolog results in the formation of HM-ACP (FIG. 5B). The second, aminomalonyl-ACP pathway, possibly involves an enzyme showing sequence similarity to adenylation domains of nonribosomal peptide synthetases (NRPSs); this enzyme, ZmaJ, contains an amino acid specificity code 45 for the activation of L-serine (L-Ser). Not wanting to be bound by the following theory, it is possible that ZmaJ tethers L-Ser to ZmaH, and the seryl-ACP is then oxidized to AM-ACP (FIG. 5C). There is only one homolog of FkbK, the enzyme that catalyzes the first oxidation of glyceryl-ACP, 50 suggesting that ZmaG catalyzes the first oxidation step in both pathways (FIG. 5B, C).

Biochemical and mass spectral approach were used to investigate whether HM-ACP and AM-ACP formation could be reconstituted in vitro. For this analysis, each protein was 55 overproduced in E. coli as an N-terminally histidine-tagged protein and purified to near homogeneity using nickel-chelate chromatography (FIG. 10). Using these purified proteins, each pathway was tested for in vitro reconstitution. FIG. 10 is an image showing analysis of purified proteins by SDS-PAGE 60 (12%) followed by Coomassie blue staining. The amount of protein loaded in each lane was as follows: 25 µg ZmaD and ZmaH; 4 µg ZmaE, ZmaG, and Zmal; 2 µg ZmaN; 3 µg ZmaJ. The same molecular weight markers were loaded in the first and sixth lanes, with the kDa of each protein marker noted on 65 the left. ZmaG is shown twice due to its proposed involvement in both HM-ACP and AM-ACP formation.

22

Reaction mixtures (130 or 260 µl) contained the following components: 10 µM glyceryl-ZmaD, 58 mM Tris pH 7.5, 8 mM MgCl₂, 0.8 mM TCEP, 385 µM CoA, 0.8 µM Sfp, 250 μM D(-)₃—PG, 5 mM ATP, 1 μM ZmaN, 1 μM ZmaG, 200 µM NAD+, 1 µM ZmaE, and 100 µM FAD. The reaction mixture was incubated at 22° C. for 1 hour prior to injection onto an HPLC. Reactions were repeated without ZmaG,

ZmaE, or replacing ZmaE with 1 μ M Zmal. The proposed pathway for HM-ACP formation involves tethering a substrate to the 4'-phosphopantetheinyl (4'-Ppant) prosthetic group of the ACP ZmaD, followed by modification of the tethered intermediate (FIG. 5B). Using HPLC and MALDI-TOF MS analysis, it was determined that the ZmaD purified from E. coli lacked the required prosthetic group (FIG. 6; Table 1).

FIG. 6 illustrates HPLC analysis of ZmaD. Representative HPLC traces of reaction mixtures containing (A) apo-ZmaD; (B) apo-ZmaD, Sfp; (C) apo-ZmaD, Sfp, ZmaN; and (D) apo-ZmaD, Sfp, ZmaN, ZmaG, ZmaE, are shown. Protein elution was monitored at 220 nm. Arrows identify the peak associated with ZmaD derivatives, which were collected and analyzed by MS. The letters above absorbance peaks identify the elution of a protein from the reaction mixture: S, Sfp; N, ZmaN; E, ZmaE; G, ZmaG.

To generate holo-ZmaD, in vitro phosphopantetheinylation was performed using the 4'-Ppant transferase Sfp. HPLC and MALDI-TOF MS analysis determined that Sfp converted most of the apo-ZmaD to holo-ZmaD (FIG. 6; Table 1).

Not wanting to be bound by the following theory, FkbH is proposed to recognize a glycolytic intermediate, dephosphorylate it, and tether it to its partner ACP to form glyceryl-ACP (FIG. 5A). The most likely substrate for FkbH is 1,3-bisphosphoglycerate (1,3-bPG). It was thus determined whether ZmaN would catalyze the formation of glyceryl-ZmaD in the presence of 1,3-bPG. In this example, the formation of glyceryl-ZmaD can be detected by a change in the elution time of holo-ZmaD from the HPLC and a change in its mass as detected by MALDI-TOF MS. Although there is no commercial source of 1,3-bPG, enzymatic synthesis can be achieved using 3-phosphoglycerate (3-PG), ATP, and 3-PG phosphokinase (PK). Incubation of these components with ZmaN and holo-ZmaD did result in a shift in holo-ZmaD elution time; however, this shift did not require the addition of 3-PGPK (FIG. 6). This suggested either the substrate for ZmaN is 3-PG, or the reaction mixtures were contaminated with an unidentified source of 3-PGPK and the substrate was the resulting 1,3-bPG. Consistent with the latter hypothesis, the rate of holo-ZmaD modification was enhanced when the 3-PGPK was added to the reaction (1.44 nmol min-1 with 3-PGPK, 0.08 nmol min-1 without 3-PGPK). Furthermore, the equivalent change in elution time of holo-ZmaD was observed when glyceraldehyde-3-phosphate dehydrogenase (GAPDH) was used to convert glyceraldehyde-3-phosphate to 1,3-bPG. Based on these observations, 1,3-bPG is the substrate for ZmaN-catalyzed modification of holo-ZmaD.

To determine whether the modified holo-ZmaD was glyceryl-ZmaD, the purified ZmaD derivatives from the reactions containing the contaminating kinase and the GAPDH were analyzed by MALDI-TOF MS. The mass of holo-ZmaD had shifted to be consistent with the formation of glyceryl-ZmaD (Table 1). Importantly, holo-ZmaH was not a substrate for ZmaN-catalyzed formation of glyceryl-ACP, suggesting ZmaN specifically recognizes holo-ZmaD.

A mass consistent with 3-phosphoglyceryl-ZmaD was not detected, suggesting the phosphatase activity of ZmaN occurs prior to the acylation of holo-ZmaD. The 3-phosphoryl group

may be extraneous since it plays no obvious role in the HM-ACP pathway. Its presence is likely because 1,3-bPG is the most readily available glyceryl primary metabolite containing an activated acid, thereby requiring the removal of the 3-phosphoryl group prior to downstream reactions. ZmaN may coordinate this phosphatase activity with its acyltransferase activity. ZmaN and its homologs contain the DXDX (T/V) motif of the phosphatase members of the haloacid dehalogenase superfamily of hydrolases. During catalysis, these enzymes remove the phosphate from the substrate by 10 first forming a phosphoaspartyl intermediate, then hydrolyzing the phosphate from the enzyme. Structural analyses of members of this enzyme superfamily suggest the phosphoaspartyl formation is associated with a conformation change of the enzyme. The phosphoaspartyl intermediate in ZmaN 15 catalysis may alter the conformation of ZmaN to enhance its interactions with holo-ZmaD once the 3-phosphoryl group is removed from the substrate, thereby coordinating the phosphatase and acyltransferase activities.

ZmaG and ZmaE are predicted to catalyze the oxidation of 20 glyceryl-ZmaD to HM-ZmaD (FIG. **5**B). These enzymes were incubated independently or together with their appropriate coenzymes along with glyceryl-ZmaD. A subtle change in elution time of glyceryl-ZmaD was observed (FIG. **6**); this change required both ZmaG and ZmaE. Indepen-25 dently, neither enzyme was found to modify the glyceryl-ZmaD intermediate. Replacement of ZmaE with Zmal also resulted in a change in elution time and mass, suggesting that either FkbI homolog may be involved in HM-ACP formation.

Analysis of the purified ZmaD-tethered product from the 30 ZmaG/ZmaE reaction by MALDI-TOF MS detected a mass consistent with the decarboxylated form of HM-ZmaD, glycolyl-ZmaD (Table 1). This decarboxylation could be the result of the instability of the product under the assay conditions or due to the sample preparation and ionization process 35 for MALDI-TOF MS. However, the detection of glycolyl-ZmaD is indicative of the formation of HM-ZmaD.

To more directly identify the ZmaD product of each reaction and to investigate whether an alternative MS technique could detect the HM-ZmaD final product, ESI-FT-ICR-MS 40 was used to analyze the ZmaD products. The intact mass spectra collected showed mass shifts consistent with the formation of holo-ZmaD (+340 Da), glyceryl-ZmaD (+426 Da), HM-ZmaD (+442 Da), and glycolyl-ZmaD (+398 Da) (FIG. 7). MS/MS data localized the active site to the sequence GY 45 V N S, where the S is the site of 4'-Ppant, and mass shifts were confirmed through measurement of the 4'-Ppant elimination product (Insets FIG. 7). Importantly, ESI-FT-ICR-MS enabled detection and mass spectral analysis of HM-ZmaD.

These data are consistent with the in vitro reconstitution of 50 HM-ACP formation and present direct evidence for the existence of ACP-linked Type I PKS extender units. The data suggest that the substrate for both HM-ACP and MM-ACP formation is 1,3-bPG.

Formation of AM-ACP

Not wanting to be bound by the following theory, the inventors proposed that the extender unit AM-ACP accounts for the ethanolamine unit in ZMA (FIG. 1). ZmaJ, a homolog of adenylation domains of NRPSs, is proposed to recognize L-Ser and tether it onto the ACP homolog ZmaH. The seryl 60 moiety is subsequently oxidized in two steps to AM-ACP, analogous to the conversion of glyceryl-ACP to HM-ACP (FIG. **5**).

Analysis of the amino acid substrate specificity of ZmaJ by standard ATP/PPi exchange assays using L-Ser and structur- 65 ally related amino acids (L-2,3-diaminopropionate, L-Thr, Gly, and L-Cys) determined ZmaJ activated only L-Ser.

Determination of the kinetic parameters of ZmaJ for L-Ser activation yielded values expected for adenylation domains of NRPSs (K_m =1.8±0.2 mM; k_{cat} =42±2 min⁻¹). To test whether ZmaJ tethers L-Ser to ZmaH, holo-ZmaH was needed.

FIG. **8** illustrates HPLC analysis of ZmaH. Representative HPLC traces of reaction mixtures containing (A) apo-ZmaH; (B) apo-ZmaH, Sfp; (C) apo-ZmaH, Sfp, ZmaJ; (D) apo-ZmaH, Sfp, ZmaJ, ZmaG, Zmal. Each reaction also contained the required cofactors and substrates.

Protein elution was monitored at 220 nm. Arrows identify the peak associated with ZmaH derivatives, which were collected and analyzed by MS. The letters above peaks identify the elution of a protein in the reaction mixture: S, Sfp; G, ZmaG; I, ZmaI; J, ZmaJ.

Following the same protocol for the conversion of apo-ZmaD to holo-ZmaD, it was determined that a majority of ZmaH is purified from *E. coli* in its apo form, and apo-ZmaH is efficiently converted to holo-ZmaH by Sfp (FIG. **8**; Table 1). Incubation of holo-ZmaH with ZmaJ, L-Ser, and ATP resulted in a change in the holo-ZmaH elution time from the HPLC, and the mass of the purified product was consistent with the formation of seryl-ZmaH (Table 1). Importantly, ZmaJ was not able to aminoacylate holo-ZmaD, highlighting the specificity of ZmaJ for holo-ZmaH.

To test for AM-ZmaH formation, ZmaG and Zmal were added independently or together with seryl-ZmaH. Only when ZmaG and Zmal were added together, along with NAD⁺ and FAD, was a change in the seryl-ZmaH elution profile observed, as indicated by a broadening of the seryl-ZmaH peak (FIG. 8). ZmaE, the homolog of Zmal from the HM-ZmaD pathway, could not replace Zmal. These data suggest Zmal is specific for AM-ZmaH formation while ZmaE is involved in HM-ZmaD formation. Analysis of the ZmaG/ Zmal-modified seryl-ZmaH derivative by MALDI-TOF MS was consistent with the formation of glycyl-ZmaH, the product expected if AM-ZmaH becomes decarboxylated, along with unreacted seryl-ZmaH (Table 1). Longer incubation of the reaction resulted in nearly complete conversion of seryl-ZmaH to glycyl-ZmaH.

The observed decarboxylation product could be due to the instability of the AM-ZmaH or to the decarboxylation caused by the MALDI-TOF MS analysis as discussed above with HM-ZmaD. To identify more directly the ZmaH-tethered products of each reaction, ESI-FT-ICR-MS analysis was performed on ZmaH purified from each reaction mixture.

FIG. **9** is an ESI-FT-ICR-MS spectra of the intermediates in AM-ZmaH formation. Top of FIG. **9** depicts ZmaH intermediates of interest (from left to right: apo-, holo-[+340 Da], glycyl-[+397 Da], seryl-ZmaH [+427 Da] and alignment to the representative peaks in the mass spectra as indicated by vertical dashed lines. Shown in FIG. **9** are the loading and corresponding mass shifts (825-865 m/z, +14 ions converted to mass scale) of: (A) apo-ZmaH; (B) holo-ZmaH; (C) seryl-ZmaH; (D) glycyl-ZmaH; asterisks indicate signals arising from artifactual adduction: sodium (+22 Da), potassium (+38 Da), phosphate (+98 Da), and oxidation of Met/Cys residues (+16 Da). Insets show mass spectra and structures of 4'-Ppant elimination product.

The intact mass spectra collected showed mass shifts consistent with the formation of holo-ZmaH (+340 Da), seryl-ZmaH (+427 Da), and glycyl-ZmaH (+397 Da) (FIG. 9). MS/MS data localized the active site to the sequence GLVNS (SEQ ID NO:14), where the S is the site of 4'-Ppant, and mass shifts were confirmed through measurement of the 4'-Ppant elimination product (see inset in FIG. 9). To address the lack of observable AM-ZmaH and lack of conversion of all of the seryl-ZmaH, the seryl-ZmaH was incubated for 5 or 40 min with ZmaG and Zmal. After 40 min, the seryl-ZmaH was almost completely converted to glycyl-ZmaH (FIG. 11).

FIG. 11 is ESI-FT-ICR-MS analysis of AM-ZmaH reactions. The top of FIG. 11 depicts ZmaH intermediates of interest (from left to right: holo-[+340], glycyl-[+397 Da], 5 seryl-ZmaH [+427 Da]) and alignment to the representative peaks in the mass spectra as indicated by vertical dashed lines. Shown are the loading and corresponding mass shifts (825-865 m/z, +14 ions) of 5 min reaction (FIG. 11A), and of 40 min reaction (FIG. 11B). AM-ZmaH, however, was not 10 detected.

The finding of glycyl-ZmaH using both MS approaches suggests assay conditions cause the decarboxylation of AM-ZmaH. This finding is not surprising based on the high level of spontaneous decarboxylation that occurs with aminoma- 15 lonate. Under acidic conditions this decarboxylation is very rapid. The HPLC assays conditions included 0.1% TFA in the solvents to function as an ion-pairing agent to enhance the resolution of proteins eluting from the HPLC. The presence of TFA in the solvents reduces the pH of the solvents to 2.0_{-20} and would likely expedite the decarboxylation of AM-ACP to glyceryl-ACP. Analysis of reaction mixtures directly by MS without prior HPLC separation also detected a mass consistent with glycyl-ZmaH. The presence of glycyl-ZmaH is indicative of AM-ZmaH formation.

the polyketide. FIG. 12 is a schematic representation of the portion of the ZMA nonribosomal peptide synthetase (NRPS) and Type I PKS. Each circle represents a catalytic domain, with the NRPS or PKS extender unit tethered to the cognate peptidyl carrier protein (PCP) or ACP domain and identified above it. The grey circles represent the AT and ACP domains of interest. Numbering identifies the extender unit for better correlation to the final ZMA structure. Abbreviations for domains: A, adenylation; PCP, peptidyl carrier protein; KS, ketosynthase; KR, ketoreductase; C, condensation.

To test this possibility in vitro characterization of ZmaF and four different derivatives of ZmaA can be used. The four derivatives of ZmaA include the wild-type enzyme along with three derivatives containing mutations that disrupt the func-tion of ACP1 (ZmaA-ACP1^M), ACP2 (ZmaA-ACP2^M), and the AT (ZmaA-AT^M). These ZmaA derivatives can be used in combination with ZmaF, [14C]-HM-ACP, and [14C]-AM-ACP extender units to identify which AT domain recognizes each extender unit, and to which ACP domain each extender unit is tethered. This can be determined by identifying the enzymes and domains required for the tethering of [¹⁴C]-HM and [¹⁴C]-AM onto ZmaA.

FIG. 12 is a schematic representation of the portion of the ZMA nonribosomal peptide synthetase (NRPS) and Type I PKS. Each circle represents a catalytic domain, with the

The data presented here are consistent with the formation of the AM-ACP extender unit. The enzyme that catalyzes the first oxidation of both glyceryl-ZmaD and seryl-ZmaH has no selectivity between the two intermediates: however, the second oxidation is catalyzed by a pathway-specific dehydroge-60 nase. The formation of AM-ACP is the first known example of an amino acid being converted to a PKS extender unit. Identification of AT Domains that Recognize and Incorporate the HM-ACP and AM-ACP Extender Units During ZMA Biosynthesis

ZmaA and ZmaF contain the enzymatic domains for the incorporation of HM-ACP and AM-ACP extender units into

NRPS or PKS extender unit tethered to the cognate peptidyl carrier protein (PCP) or ACP domain and identified above it. The grey circles represent the AT and ACP domains of interest for this proposal. Numbering identifies the extender unit for better correlation to the final ZMA structure. Abbreviations for domains: A, adenylation; PCP, peptidyl carrier protein; KS, ketosynthase; KR, ketoreductase; C, condensation.

ZmaF and the ZmaA derivatives containing affinity tags can be overproduced, for example in Escherichia coli. These enzymes can be purified using nickel-chelate chromatography. The mutant ZmaA proteins can be generated using standard site-directed mutagenesis techniques on zmaA. [¹⁴C]-

65

HM-ACP and $[^{14}C]$ -AM-ACP can be generated using the reconstituted extender unit biosynthetic pathways by starting the reactions with $[^{14}C]$ -3-phosphoglycerate or $[^{14}C]$ -L-serine, respectively (FIG. **4**).

The different ZmaA derivatives can be incubated independently with [14 C]-HM-ACP or [14 C]-AM-ACP in the presence or absence of ZmaF. After termination of the reactions, the proteins in each reaction are separated by SDS-PAGE, the proteins visualized by Coomassie blue staining, and the ZmaA derivatives containing radiolabeled extender units are 10 identified by phosphoimaging of the stained gel. Not wanting to be bound by the following theory, based on the inventors' model for ZMA biosynthesis, [14 C]-HM can be detected on the wild-type ZmaA and ZmaA-ACP1^M, but not on ZmaA-ACP2^M or ZmaA-AT^M regardless of whether ZmaF is 15 present. However, [14 C]-AM can be detected on wild-type ZmaA, ZmaA-ACP2^M, and ZmaA-AT^M, and will require ZmaF. The hypotheses for the domains involved in HM-ACP and AM-ACP utilization are based on bioinformatics analysis of the ZMA biosynthetic pathway. Alternatives to this model 20 are possible, and can be detected by the above experiments.

Thus, the AT domains and their partner ACP domains that are involved in the recognition and incorporation of HM-ACP and AM-ACP extender units can be identified. Furthermore, domains can be identified that can be used for investigating the metabolic engineering of other Type I PKSs to create novel, potentially clinically useful molecules. Metabolic Engineering of a Portion of the Erythromycin Type

I PKS to Incorporate HM-ACP or AM-ACP Extender Units

A modified version of the erythromycin PKS can be used, 30 which contains only its first three modules fused to a thioesterase domain. This construct, called DEBS1-Te, naturally condenses and cyclizes one propionyl-CoA starter unit with two methylmalonyl-CoA extender units into a triketide lactone (FIG. **13**). This construct is commonly used for initial 35 investigations into metabolic engineering of Type I PKSs.

FIG. **13** is a schematic representation of wild-type DEBS1-Te and its derivatives that can be constructed according to this invention. The structures on the right are the established or proposed triketide lactone structures produced by the Type I 40 PKSs. Circles represent PKS domains. Grey circles represent ZMA PKS domains used to engineer DEBS1-Te. Black circle represents inactivated AT domain. Abbreviations are as defined in text and FIG. **7** with the addition of Te, thioesterase. Bars and numbers under DEBS1-Te denote the three modules 45 of the Type I PKS.

Derivatives of DEBS1-Te can be engineered with the ability to incorporate either HM-ACP or AM-ACP as the first extender unit. Importantly, the sites for inserting noncognate domains into the erythromycin PKS have been previously 50 defined (McDaniel et al., 1999, Proc. Natl. Acad. Sci. USA 96: 1846-1851; Hans et al., 2003, J. Am. Chem. Soc. 125: 5366-5374); thus, the construction of these engineered derivatives is straightforward. One PKS derivative can have the natural methylmalonyl-CoA-specific AT domain switched with the 55 HM-ACP-specific AT domain from ZmaA, resulting in a hybrid Type I PKS that can generate 2-methyl-3,4,5-trihydroxy heptanoic acid γ -lactone (FIG. 13). A second PKS derivative can have the natural ACP domain of module 2 replaced by the ACP1 domain of ZmaA, and the natural AT 60 domain of module 2 inactivated by site-directed mutagenesis. This modified DEBS1-Te can incorporate AM-ACP when ZmaF is added in trans, thereby generating 2-methyl-3,5dihydroxy-4-amino heptanoic acid y-lactone (FIG. 13).

The modified DEBS1-Te PKSs can be overproduced in 65 *Streptomyces coelicolor* and the proteins can be purified using established protocols (Kao et al., 1994, *Science* 265:

28

509-512). The purified proteins can be incubated with propionyl-CoA, methylmalonyl-CoA, and [14C]-HM-ACP or ^{[14}C]-AM-ACP along with the required cofactors. ZmaF can also be added to those reactions containing [¹⁴C]-AM-ACP. The products of the reactions can be separated by thin-layer chromatography as previously described for triketide lactone separation, and detected by phosphorimaging. If a new product is detected, the reaction can be scaled up with nonradioactive substrates, and the triketide lactones can be purified by HPLC and analyzed by mass spectrometry. Examples of predicted products are shown in FIG. 13. The overproduction of these proteins is straightforward based on previous success with this method (Pieper et al., 1995, Nature 378: 263-266). However, one skilled in the art is aware that a gene from B. cereus will have a different codon usage compared to S. coelicolor, which may change the production levels of the engineered enzymes. If desired, the codon usage of the inserted portions of zmaA can be changed to more closely match that for actinomycetes following established protocols (Menzella et al., 2005, Nature Biotech. 23: 1171-1176).

Thus, in some embodiments, the conditions for the engineering of a model Type I PKS to incorporate either HM-ACP or AM-ACP are provided. This is the first known example of engineering a PKS to incorporate a noncognate extender unit other than malonyl-CoA or methylmalonyl-CoA. Additionally, the triketide lactones are first known examples of hydroxyl or amino moiety functionality being introduced into a noncognate polyketide backbone.

Incorporation of Hydroxymalonyl-Acyl Carrier Protein (HM-ACP)

Cloning of the zwittermicin A (ZMA) biosynthetic genes. The genes zmaD, zmaE, zmaG, and zmaN were PCR amplified from B. cereus UW85 chromosomal DNA or the supernatant of boiled overnight cultures of E. coli DH10b/ pBelo11-ZmA, a BAC vector containing the ZMA gene cluster. PCR products for zmaD, zmaE, zmaG, and zmaN were cloned into pET28b (Novagen) (kanamycin-resistant) using NdeI and either HindIII. SacI. or XhoI restriction sites. The gene zmaA was amplified as two overlapping fragments. consisting of a 4.5 kb fragment containing a naturally-occurring SmaI restriction site at the 3' end and a 5.5 kb fragment containing the SmaI restriction site at the 5' end. Both of these fragments were individually cloned into pCRBluntII-TOPO (Invitrogen) (kanamycin-resistant). The first fragment was subcloned to pET15b (ampicillin-resistant) using NdeI and NotI, and the second fragment was then subcloned into this construct using SmaI and XhoI to generate pET15b-zmaA. The DNA encoding the acyl transferase domain (AT) and second acyl carrier protein (ACP) domain of zmaA (ACP2) was PCR amplified from pET15b-zmaA. The AT domain was cloned into pET30a (kanamycin-resistant) using NcoI and XhoI, and ACP2 was cloned into pET28b using NdeI and XhoI. All clones were verified by sequencing at the University of Wisconsin Biotechnology Sequencing Center.

Heterologous overproduction of enzymes. All expression constructs were transformed into competent *Escherichia coli* BL21 (λ DE3) cells for heterologous overexpression. For overproduction of ZmaD, ZmaG, ZmaN, AT, and ACP2, cells were grown at 25° C. with vigorous shaking in LB medium supplemented with 50 µg/mL kanamycin; when the OD₆₀₀ reached 0.4-0.6, the temperature was dropped to 15° C. After growing at 15° C. for 1.5-2.5 h, isopropyl-D-thiogalactopyranoside (IPTG) was added to a final concentration of 60-300 µM, and the cells were grown for an additional 16 h at 15° C. For overproduction of ZmaE, cells were grown at 25° C. with vigorous shaking for 24 h in LB medium supplemented with 50 µg/mL kanamycin. Cells were harvested by centrifugation.

Purification of proteins. E. coli cells containing the expres- 5 sion constructs for zmaD, zmaE, zmaG, zmaN, AT, and ACP2 were resuspended in histidine-tag purification buffer (for ZmaG: 20 mM Tris-Cl [pH 8.0], 300 mM NaCl, 10% [w/v] sucrose; for all other proteins: 20 mM Tris-Cl [pH 8.0], 300 mM NaCl, 10% [v/v] glycerol). The resuspended cells were 10 broken by sonication, and cell debris was removed by centrifugation. Imidazole was added to the cell-free extract at a final concentration of 5 mM, and the extract was incubated with 1-2 mL of Ni-NTA agarose resin (Qiagen) for 1-2 hours at 4° C. with gentle shaking. The resin was collected by 15 centrifugation and packed into a column. The resin was washed with histidine-tag buffer containing imidazole (5 mM), and stepwise elutions were performed with histidinetag buffer containing imidazole at final concentrations of 20, 40, 60, 100, and 250 mM. SDS-PAGE analysis of the col- 20 lected fractions was performed. Fractions containing purified protein (as determined by Coomassie Blue-staining of the gel) were pooled and dialyzed at 4° C. in 1 L dialysis buffer (for ZmaD, ZmaE, ZmaN, ACP2: 50 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, and 10% [v/v] glycerol; for ZmaG: 50 25 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, and 10% [w/v] sucrose; for AT: 50 mM Tris-Cl [pH 8 at 4° C.], 50 mM NaCl, and 10% $\left[v/v\right]$ glycerol). ZmaE was dialyzed further in high salt buffer (50 mM Tris-Cl [pH 8 at 4° C.], 300 mM NaCl, and 10% [v/v] glycerol) at 4° C.

Purified ZmaD, ZmaE, ZmaG, ZmaN, and ACP2 were concentrated using Millipore Centriprep protein concentrators, flash frozen with liquid nitrogen, and stored at -80° C.

The AT domain was concentrated using a Millipore Centriprep protein concentrator and then loaded onto BioRad 35 BioScale Mini UNOSphere Q (5 mL) column for further purification. The column was washed with Buffer A (50 mM Tris-Cl [pH 8 at 4° C.], 50 mM NaCl, and 10% [v/v] glycerol), and the protein was eluted using a gradient of 0-100% B (50 mM Tris-Cl [pH 8 at 4° C.], 1 M NaCl, and 10% [v/v] 40 glycerol) (flow rate 3 mL/min). Fractions containing the AT domain were pooled and dialyzed in 1 L dialysis buffer (50 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, and 10% [v/v] glycerol) at 4° C. The protein was then concentrated as before, flash frozen with liquid nitrogen, and stored at -80° C. 45 Protein concentrations were determined using the calculated molar extinction coefficients (ZmaD, 2560 M⁻¹ cm⁻¹; ZmaE, 44410 M⁻¹ cm⁻¹; ZmaG, 21180 M⁻¹ cm⁻¹; ZmaN, 41070 M^{-1} cm⁻¹; ACP2, 27880 M^{-1} cm⁻¹; AT, 50810 M^{-1} cm⁻¹).

Formation of HM-ACP2. Reaction mixtures contained the 50 following components: 75 mM Tris-Cl (pH 7.5), 10 mM MgCl₂, 1 mM TCEP, 500 μ M CoA, 12.5 μ M ACP2, 1 μ M ZmaD, 1 μ M Sfp, 1 μ M ZmaN, 200 μ M NAD⁺, 100 μ M FAD, 1 μ M ZmaG, 1 μ M ZmaE, 1 μ M AT, 1 U 3-phosphoglycerate phosphokinase (3-PGPK, Sigma), 250 μ M 3-phosphoglycer-55 ate (3-PG, Sigma), and 5 mM ATP. Prior to the addition of ZmaN, NAD⁺, FAD, ZmaG, ZmaE, AT, 3-PGPK, 3-PG, and ATP, the ACPs ZmaD and ACP2 were allowed to react with Sfp for an hour at room temperature to become phosphopantetheinylated. The complete reaction was initiated with the 60 addition of ATP, and the reaction was incubated at room temperature for 45 minutes. Control reactions lacking ACP2, ZmaD, ZmaN, ZmaG, ZmaE, AT, and ATP were performed, as were control reactions in which ZmaF replaced AT.

HPLC analysis of reaction products. HPLC analysis of 65 reaction products was performed with a Vydac (Hesperia, Calif.) C18 peptide column (250×4.6 mm). Two-hundred

microliters of the reactions were injected, and the reaction products were separated using a 20-80% acetonitrile/0.1% TFA gradient over 20 min at a flow rate of 1 mL/min. Elution was monitored at 220 nm.

MALDI-TOF MS analysis of reaction products. The reaction products were collected as they eluted from the HPLC, flash-frozen with $CO_2(s)$ /ethanol, and lyophilized overnight. Lyophilized samples were resuspended in double-distilled water and added to the sinipinic acid matrix (10 mg/L in 50% acetonitrile/0.05% TFA). MALDI-TOF MS analysis was performed using a Voyager Biospectrometry Workstation (DE-Pro; Applied Biosystems, Foster City, Calif.) in linear, positive mode. Cytochrome c, apomyoglobin, and aldolase (Sigma) were used as standards for calibration.

Incorporation of Aminomalonyl-ACP (AM-ACP)

Cloning of the ZMA biosynthetic genes. The genes zmaA and zmaG were cloned as described for HM-ACP incorporation. The genes zmaF, zmaH, zmaI, and zmaJ were PCR amplified from *B. cereus* UW85 chromosomal DNA or the supernatant of boiled overnight cultures of *E. coli* DH10b/ pBelo11-ZmA, a BAC vector containing the ZMA gene cluster.

The PCR product for zmaF was cloned into pCRBluntII-TOPO and cloned into pET28b using NdeI and HindIII. The PCR products for zmaH, zmaI, and zmaJ were cloned into PGEM®-T Easy (Promega) (ampicillin-resistant) and subcloned into pET28b using NdeI and XhoI restriction sites. The DNA encoding the first ACP domain of zmaA was PCR amplified from pET15b-zmaA, cloned into pCRBluntII-TOPO, and subcloned into pET28b using NdeI and HindIII. All clones were verified by sequencing at the University of Wisconsin Biotechnology Sequencing Center.

Heterologous overproduction of enzymes. ZmaG was heterologously overproduced as described for HM-incorporation. All expression constructs were transformed into competent *Escherichia coli* BL21 (λ DE3) cells for heterologous overexpression. For overproduction of ZmaA, cells were grown at 30° C. with vigorous shaking in LB medium containing 100 µg/mL ampicillin. When the OD₆₀₀ reached 0.8, the temperature was dropped to 15° C. After growing at 15° C. for 1.5 h, IPTG was added at a final concentration of 200 μM. Cells were grown for an additional 7.5 h and harvested. For overproduction of ZmaF, ZmaH, ZmaJ, and ACP1, cells were grown at 25° C. with vigorous shaking in LB medium supplemented with 50 μ g/mL kanamycin; when the OD₆₀₀ reached 0.4-0.6, the temperature was dropped to 15° C. After growing at 15° C. for 1.5-2.5 h, IPTG was added to a final concentration of 60-300 µM, and the cells were grown for an additional 16 h at 15° C. For overproduction of Zmal, cells were grown at 25° C. with vigorous shaking for 24 h in LB medium supplemented with 50 µg/mL kanamycin. Cells were harvested by centrifugation.

Purification of proteins. ZmaG was purified as described above for HM-ACP incorporation. *E. coli* cells containing the expression constructs for zmaA, zmaF, zmaH, zmaI, zmaJ, and ACP1 were resuspended in histidine-tag purification buffer (20 mM Tris-Cl [pH 8.0], 300 mM NaCl, 10% [v/v] glycerol). The resuspended cells were broken by sonication, and cell debris was removed by centrifugation. Imidazole was added to the cell-free extract at a final concentration of 5 mM, and the extract was incubated with 1-2 mL of Ni-NTA agarose resin (Qiagen) for 1-2 hours at 4° C. with gentle shaking. The resin was collected by centrifugation and packed into a column. The resin was washed with histidine-tag buffer containing imidazole (5 mM), and stepwise elutions were performed with histidine-tag buffer containing imidazole at final concentrations of 20, 40, 60, 100, and 250 mM. SDS-PAGE analysis of the collected fractions was performed. Fractions containing purified protein (as determined by Coomassie Blue-staining of the gel) were pooled and dialyzed at 4° C. in 1 L dialysis buffer (for ZmaH and ZmaJ: 50 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, and 10% [v/v] glycerol; for ACP1 and ZmaF: 50 mM Tris-Cl [pH 8 at 4° C.], 50 mM NaCl, and 10% [v/v] glycerol); for Zmal: 50 mM Tris-Cl [pH 8 at 4° C.], 300 mM NaCl, and 10% [v/v] glycerol; for ZmaA: 50 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, and 10% [v/v] glycerol, 1 mM EDTA, and 20 µM PMSF). ACP1 was dialyzed 10 further in a buffer containing higher salt concentration (50 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, and 10% [v/v] glycerol). Zmal was dialyzed further in high salt buffer containing FAD (50 mM Tris-Cl [pH 8 at 4° C.], 300 mM NaCl, 10% [v/v] glycerol, and 100 μ M FAD) and then in high salt 15 buffer lacking FAD. Purified ZmaH, Zmal, ZmaJ, and ACP1 were concentrated using Millipore Centriprep protein concentrators, flash frozen with liquid nitrogen, and stored at -80° C. Purified ZmaA was flash frozen with liquid nitrogen and stored at -80° C. ZmaF was loaded onto 2 BioRad Bio-20 Scale[™] Mini DEAE Affi-Gel Blue cartridges (5 mL) for further purification. The column was washed with Buffer A (50 mM Tris-Cl [pH 8 at 4° C.], 50 mM NaCl, and 10% [v/v] glycerol), and the protein was eluted using a gradient of 0-100% B (50 mM Tris-Cl [pH8 at 4° C.], 1 M NaCl, and 10% 25 [v/v] glycerol) (flow rate 3.5 mL/min). Fractions containing ZmaF were pooled and dialyzed in 1 L dialysis buffer (50 mM Tris-Cl [pH 8 at 4° C.], 50 mM NaCl, and 10% [v/v] glycerol) at 4° C., further dialyzed in a buffer containing higher salt concentration (50 mM Tris-Cl [pH 8 at 4° C.], 100 mM NaCl, 30 and 10% [v/v] glycerol), concentrated using a Millipore Centriprep protein concentrator, and flash frozen with liquid nitrogen and stored at -80° C. Protein concentrations were determined using the calculated molar extinction coefficients (ZmaH, 2560 $\breve{M}^{-1}~cm^{-1};$ Zmal, 44770 $M^{-1}~cm^{-1};$ ZmaJ, 35 $46760 \text{ M}^{-1} \text{ cm}^{-1}$; ZmaF, 37820 $\text{M}^{-1} \text{ cm}^{-1}$).

Formation of AM-ZmaA. ZmaA and ZmaH were first converted to holo-form in separate reactions with Sfp. ZmaA was incubated at room temperature for 1.5 h in a 50 µL reaction mixture containing 75 mM Tris-Cl (pH 7.5), 10 mM MgCl₂, 40 500 µM CoA, 37.75 µL ZmaA (partially purified), and 1 µM Sfp. ZmaH was incubated at room temperature for 1 h in a 50 µL reaction mixture containing 75 mM Tris-Cl (pH 7.5), 10 mM MgCl₂, 50 µM CoA, 40 µM ZmaH, and 1 µM Sfp. AM-ZmaH was formed in a 65 µL reaction mixture contain- 45 ing 36 μL of holo-ZmaH, 100 μM [^14C(U)]-L-serine, 5 mM ATP, 200 µM NAD⁺, 100 µM FAD, 1 µM ZmaG, and 1 µM Zmal. AM-ZmaA was formed in a 120 µL reaction mixture containing 65 µL of AM-ZmaH, 50 µL holo-ZmaA, and 5 µL of ZmaF. A control reaction was set up lacking ZmaF. After 50 incubating at room temperature for 2.5 h, 30 µL of each reaction was removed to a tube containing an equal volume of $2 \times$ cracking buffer (lacking β -mercaptoethanol), and 25μ L of this mixture was loaded onto a Tris-Cl 4-15% gradient SDSpolyacrylamide gel (BioRad). The gel was stained with Coo- 55 massie, destained, dried, exposed to a phosphorimaging screen, and visualized after 9 days of exposure.

Formation of AM-ACP1. Fifty μ L reaction mixtures contained the following components: 75 mM Tris-Cl (pH 7.5), 10 mM MgCl₂, 1 mM TCEP, 500 μ M CoA, 15.96 μ L ACP2 60 (partially purified), 1 μ M ZmaH, 1 μ M Sfp, 1 μ M ZmaJ, 200 μ M NAD⁺, 100 μ M FAD, 1.5 μ M ZmaG, 1.5 μ M ZmaI, 2 μ M ZmaF, 100 μ L [¹⁴C(U)]-L-serine, and 5 mM ATP. Prior to the addition of ZmaJ, NAD⁺, FAD, ZmaG, ZmaI, ZmaF, [¹⁴C (U)]-L-serine, and ATP, the ACPs ZmaH and ACP1 were 65 allowed to react with Sfp for an hour at room temperature to become phosphopantetheinylated. The complete reaction

was initiated with the addition of ATP, and the reaction was incubated at room temperature for 1.5 h. Control reactions lacking ACP2, ZmaF, Zmal, ZmaG, and ZmaJ were performed. Parallel reaction mixtures were set up containing the same components except with 18.5 μ M instead of 1 μ M ZmaH. Thirty μ L of the reaction mixtures were removed to tubes containing an equal volume of 2× cracking buffer, and 25 μ L of the mixtures were loaded onto Tris-Cl 12% SDS-polyacrylamide gel. The gels were stained with Coomassie, destained, dried, exposed to a phosphorimaging screen, and visualized after 9 days of exposure.

Metabolic Engineering of *Saccharopolyspora erythraea* to Produce 13-Amino- or 13-Hydroxy-Erythromycin Derivatives

Saccharopolyspora erythraea naturally produces erythromycin and has been metabolically engineered by to generate structural derivatives of this antibiotic. Metabolic engineering of this strain can be used for in vivo production of erythromycin derivatives that incorporate HM-ACP and AM-ACP extender units into the polyketide backbone of this important antibiotic. Briefly, the chromosomal eryAI gene, encoding the DEBS1 Type I PKS, can be modified so that it results in the production of DEBS1 derivatives that are analogous to the DEBS1-Te constructs discussed above, but will lack the Te domain. Therefore, either HM-ACP or AM-ACP extender units can be used as the second extender unit incorporated into the erythromycin polyketide backbone. The construction of these strains is straightforward since genetic techniques commonly used for other actinomycetes are transferable to Saccharopolyspora erythraea.

While the modification of eryA1 can result in a hybrid Type I PKS, Saccharopolyspora erythaea does not naturally produce HM-ACP or AM-ACP; thus, this bacterium has to be engineered to produce these extender units. This can be accomplished, for example, by generating artificial operons expressing zmaD, E, G, and N for HM-ACP formation, or zmaG, H, I, and J for AM-ACP formation (FIG. 4). The operon for AM-ACP formation can also contain the zmaF gene, coding for the AM-ACP recognizing AT domain. The construction of these operons can follow an established protocol whereby the target genes are cloned in sequence downstream of a desired promoter, with a ribosome-binding site separating each gene (Watanabe et al., 2006, Nat. Chem. Biol. 2: 423-428). The artificial operons can then be subcloned into a vector, pSET152, which has been shown to stably integrate into the Saccharopolyspora erythraea genome (Brunker et al, 1998, Microbiology 144: 2441-2448). The resulting strains can contain an engineered eryA1 within the natural erythromycin biosynthetic gene cluster, while production of the new extender unit can be controlled by genes constitutively expressed by the integrated pSET152 vector.

The engineered *Saccharopolyspora erythraea* strains can be grown under standard conditions for optimal erythromycin production and the erythromycin derivatives can be purified from the culture supernatant using established protocols (Wilkinson et al., 2000, *Chem. Biol.* 7: 111-117). The products can be analyzed by mass spectrometry and [¹H]- and [¹³C]-NMR. In one example, using the methods of this invention, 13-amino and 13-hydroxy derivatives of erythromycin can be generated by these strains. FIG. **14** illustrates the chemical structures of erythromycin (center) and putative erythromycin derivatives generated by using metabolic engineering. Grey circle highlights the C13 position of the inserted hydroxyl or amino group.

Using the methods of this invention, it would be possible to systematically change each position of the erythromycin polyketide backbone with amino or hydroxyl moieties (FIG.

14). Each of these derivatives can then be screened for activity against M. tuberculosis, and can also be used a starting compound for downstream chemical modifications. For example, each free amino group can be modified by simply incubating the molecule with N-hydroxysuccinimide esters, which react 5 spontaneously with primary amines. There are hundreds of N-hydroxysuccinimide esters available through various chemical supply companies, raising the possibility of generating hundreds of new erythromycin derivatives. This example of the invention, with emphasis on antituberculosis 10 drugs, can be particularly relevant, as the introduction of modifications to the C12 position of erythromycin results in an antibiotic with enhanced activity against M. tuberculosis (Kanakeshwari et al., 2004, Antimicrob. Agents Chemother. 49: 1447-1454). 15

It is to be understood that this invention is not limited to the particular devices, methodology, protocols, subjects, or reagents described, and as such may vary. It is also to be understood that the terminology used herein is for the purpose of describing particular embodiments only, and is not intended to limit the scope of the present invention, which is limited only by the claims. Other suitable modifications and adaptations of a variety of conditions and parameters normally encountered in molecular biology and biochemistry, and obvious to those skilled in the art, are within the scope of this invention. All publications, patents, and patent applications cited herein are incorporated by reference in their entirety for all purposes.

SUMMARY OF SEQUENCE LISTINGS

SEQ ID NO:1 is the amino acid sequence of ZmaN.

SEQ ID NO:2 is the amino acid sequence of ZmaD.

SEQ ID NO:3 is the amino acid sequence of ZmaE.

SEQ ID NO:4 is the amino acid sequence of ZmaG.

SEQ ID NO:5 is the amino acid sequence of ZmaA.

SEQ ID NO:6 is the amino acid sequence of ZmaF.

SEQ ID NO:7 is the amino acid sequence of the KS1 domain of ZmaA.

SEQ ID NO:8 is the amino acid sequence of the KR1 domain of ZmaA.

SEQ ID NO:9 is the amino acid sequence of the ACP1 domain of ZmaA.

SEQ ID NO:10 is the amino acid sequence of the KS2 domain of ZmaA.

SEQ ID NO:1 is the amino acid sequence of the AT domain of ZmaA.

SEQ ID NO:12 is the amino acid sequence of the KR2 domain of ZmaA.

SEQ ID NO:13 is the amino acid sequence of the ACP2 domain of ZmaA.

SEQ ID NO:14 is the amino acid sequence of the ZmaH site of post-translational modification by 4'-phosphopantetheinyl group.

What is claimed is:

hybrid polyketide molecule, comprising adding and reacting aminomalonyl-acyl carrier protein (AM-ACP) in a cell-free system with

- (a) an isolated polypeptide comprising an amino acid sequence selected from the group consisting of the 20 amino acid sequence of SEQ ID NO:6 and an amino acid sequence that is at least 95% identical to SEQ ID NO:6, wherein said isolated polypeptide has the biological activity of catalyzing the incorporation of an ethanolamine subunit from AM-ACP into a polyketide; and 25
- (b) a second isolated polypeptide comprising (i) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:7 and an amino acid sequence that is at least 95% identical to SEQ ID NO:7, whereby the second isolated polypeptide has ketosyn- 30 thase activity, (ii) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:8, whereby the second isolated polypeptide has ketoreductase activity, and (iii) an amino acid sequence selected from the group consisting of the amino acid 35 sequence of SEQ ID NO:9 and an amino acid sequence that is at least 95% identical to SEQ ID NO:9, whereby the second isolated polypeptide has acyl carrier protein activity.
- wherein said isolated polypeptides of (a) and (b) incorpo- 40 rate the aminomalonyl into the hybrid polyketide molecule.

2. The method of claim 1, further comprising expressing in a host cell a polynucleotide encoding each of the isolated polypeptides selected in (a) and (b) and subsequently isolat- 45 ing the polypeptides expressed by the host cell from the host cell to use in the cell-free system.

3. A method for incorporating an aminomalonyl into a hybrid polyketide molecule, comprising adding and reacting aminomalonyl-acyl carrier protein (AM-ACP) in a cell-free 50 system with (a) an isolated polypeptide comprising an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:6 and an amino acid sequence that is at least 95% identical to SEQ ID NO:6, wherein said isolated polypeptide has the biological activity 55 a polyketide, of catalyzing the incorporation of an ethanolamine subunit from AM-ACP into a polyketide; and

- (b) a second isolated polypeptide comprising an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:5 and an amino acid 60 sequence that is at least 95% identical to SEQ ID NO:5, whereby the second isolated polypeptide has ketosynthase activity, ketoreductase activity, and acyl carrier protein activity.
- wherein said isolated polypeptides of (a) and (b) incorpo- 65 rate the aminomalonyl into the hybrid polyketide molecule.

4. The method of claim 3, further comprising expressing in 1. A method for incorporating an aminomalonyl into a ¹⁵ a host cell a polynucleotide encoding each of the isolated polypeptides selected in (a) and (b) and subsequently isolating the polypeptides expressed by the host cell from the host cell to use in the cell free system.

5. A method for incorporating a hydroxymalonyl into a hybrid polyketide molecule, comprising adding and reacting hydroxymalonyl-acyl carrier protein (HM-ACP) in a cell-free system with an isolated polypeptide comprising (a) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:10 and an amino acid sequence that is at least 95% identical to SEQ ID NO:10, (b) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:11 and an amino acid sequence that is at least 95% identical to SEQ ID NO:11, whereby the isolated polypeptide has acyltransferase activity, (c) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:12 and an amino acid sequence that is at least 95% identical to SEQ ID NO:12, whereby the isolated polypeptide has ketoreductase activity, and (d) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:13 and an amino acid sequence that is at least 95% identical to SEQ ID NO:13, whereby the isolated polypeptide has acyl carrier protein activity,

wherein said isolated polypeptide incorporates the hydroxymalonyl into the hybrid polyketide molecule.

6. The method of claim 5, further comprising expressing in a host cell a polynucleotide encoding the isolated polypeptide and subsequently isolating the polypeptide expressed by the host cell from the host cell to use in the cell free system.

7. A method for incorporating a hydroxymalonyl into a hybrid polyketide molecule comprising adding and reacting hydroxymalonyl-acyl carrier protein (HM-ACP) in a cell-free system with an isolated polypeptide comprising an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:5 and an amino acid sequence that is at least 95% identical to SEQ ID NO:5, wherein said isolated polypeptide has the biological activity of recognition, activation, and condensation of HM-ACP into

wherein said isolated polypeptide incorporates the hydroxymalonyl into the hybrid polyketide molecule.

8. The method of claim 7, further comprising expressing in a host cell a polynucleotide encoding the isolated polypeptide and subsequently isolating the polypeptide expressed by the host cell from the host cell to use in the cell free system.

9. A method for incorporating an aminomalonyl into a hybrid polyketide molecule, comprising adding and reacting aminomalonyl-acyl carrier protein (AM-ACP) in a cell-free system with an isolated polypeptide comprising an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:6 and an amino acid sequence that is at least 95% identical to SEQ ID NO:6, wherein said isolated polypeptide has the biological activity of catalyzing the incorporation of an ethanolamine subunit from AM-ACP into a polyketide,

wherein the aminomalonyl is incorporated into the hybrid 5 polyketide molecule.

10. The method of claim 9, further comprising reacting the AM-ACP in the cell-free system with a second isolated polypeptide comprising one or more of (a) an amino acid sequence selected from the group consisting of the amino 10 acid sequence of SEQ ID NO:7 and an amino acid sequence that is at least 95% identical to SEQ ID NO:7, whereby the second isolated polypeptide has ketosynthase activity; (b) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:8 and an amino acid 15 sequence that is at least 95% identical to SEQ ID NO:8, whereby the second isolated polypeptide has ketoreductase activity; and (c) an amino acid sequence selected from the group consisting of the amino acid sequence of SEQ ID NO:9 and an amino acid sequence that is at least 95% identical to 20 SEQ ID NO:9, whereby the second isolated polypeptide has acyl carrier protein activity.
