### (57) ABSTRACT

The present invention relates to methods for reprogramming a somatic cell to pluripotency by administering into the somatic cell at least one or a plurality of potency-determining factors. The invention also relates to pluripotent cell populations obtained using a reprogramming method.

### SOMATIC CELL REPROGRAMMING

#### CROSS-REFERENCE TO RELATED APPLICATIONS

This application is a continuation of U.S. application Ser. No. 12/053,440, filed Mar. 21, 2008, which claims the benefit of U.S. Provisional Patent Application No. 60/919, 687, filed Mar. 23, 2007; U.S. Provisional Patent Application No. 60/974,980, filed Sep. 25, 2007; and U.S. Provisional Patent Application No. 60/989,058, filed Nov. 19, 2007, each of which is incorporated herein by reference as if set forth in its entirety.

#### STATEMENT REGARDING FEDERALLY SPONSORED RESEARCH OR DEVELOPMENT

This invention was made with government support under RR000167 and GM069981 awarded by the National Insti-<sup>20</sup> tutes of Health. The government has certain rights in the invention.

#### BACKGROUND

Embryonic stem (ES) cells can grow indefinitely while maintaining pluripotency and can differentiate into cells of all three germ layers (Evans & Kaufman, Nature 292:154-156 (1981)). Human ES cells will be useful in treating a host of diseases, such as Parkinson's disease, spinal cord injury 30 and diabetes (Thomson et al., Science 282:1145-1147 (1998)). Scientists have sought technical solutions to avoid the current method of generating ES cells from blastocyst cells and to avoid anticipated tissue rejection problems following transplantation into patients. One desirable way to 35 accomplish these solutions would be to generate pluripotent cells directly from somatic cells of a post-natal individual.

Somatic cells can be reprogrammed by transferring their nuclear contents into oocytes (Wilmut et al., Nature 385: 810-813 (1997)) or by fusion with ES cells (Cowan et al., Science 309:1369-1373 (2005)), indicating that unfertilized eggs and ES cells contain factors that confer totipotency or pluripotency in somatic cells. (Wilmut et al., Nature 385: 810-813 (1997)) or by fusion with ES cells (Cowan et al., Stem Cells 22:522-530 (2004); and Matsuda T, et al., EMBO J. 18:4261-4269 (1999)). Similarly, while bone morphogenetic proteins (BMPs) together with LIF support mouse ES cell self-renewal at

Likewise, Yu et al. showed that cells derived by in vitro differentiation from an H1 Oct4 knock-in ES cells did not 45 express EGFP, but that EGFP expression was restored upon cell-cell fusion with human ES cells. Yu et al., Stem Cells 24:168-176 (2006), incorporated herein by reference as if set forth in its entirety). Therefore, Yu et al. demonstrated that differentiated cells can become pluripotent via cell-cell 50 fusion with human ES cells. Regardless of the differentiated cell type, upon fusion with undifferentiated human ES cells, ES cell specific antigens and marker genes were expressed and differentiation-specific antigens were no longer detectable in the fused hybrid cells. Advantageously, EGFP 55 expression was re-established in the hybrid cells, providing a convenient marker for re-establishment of pluripotent stem cell status. When the hybrid cells formed embryoid bodies (EBs), genes characteristic of all three germ layers and extra-embryonic tissues were up-regulated, indicating that 60 the hybrid cells had a potential to differentiate into multiple lineages.

Although the transcriptional determination of pluripotency is not fully understood, several transcription factors, including Oct 3/4 (Nichols et al., Cell 95:379-391 (1998)), 65 Sox2 (Avilion et al., Genes Dev. 17:126-140 (2003)) and Nanog (Chambers et al., Cell 113:643-655 (2003)) are

involved in maintaining ES cell pluripotency; however, none is sufficient alone to specify ES cell identity.

Chambers & Smith (EP 1 698 639 A2, (2002)) maintained pluripotent murine cells without a feeder layer or feeder cell extract and without a gp130 cytokine by introducing vectors that encode or activate differentiation-suppressing factors, but did not convert differentiated cells into a pluripotent state.

More recently, Takahashi & Yamanaka introduced four factors (i.e., Oct3/4, Sox2, c-Myc and Klf4) into mouse ES cells and mouse adult fibroblasts cultured under conditions suitable for mouse ES cell culture to obtain induced pluripotent stem (iPS) cells that exhibited mouse ES cell morphology and growth properties and expressed mouse ES cell marker genes (Takahashi & Yamanaka, Cell 126:663-676 (2006)). Notably, exogenous Oct-4 introduced into the mouse fibroblasts resulted in only marginal Oct-4 expression. Subcutaneous transplantation of iPS cells into nude mice resulted in tumors containing a variety of tissues from all three germ layers. Following injection into blastocysts, iPS cells contributed to mouse embryonic development. However, c-Myc, which was necessary for pluripotent induction, is an oncogene. Likewise, Klf4 is an oncogene. These data demonstrate that pluripotent cells can be directly generated from mouse fibroblast cultures by adding only a few defined factors using a retroviral transduction. However, as described infra, the set of factors used to produce iPS cells from differentiated mouse cells was insufficient to reprogram human somatic cells to pluripotency using lentiviral vectors without introducing additional changes to the cells.

One could hypothesize that factors that can reprogram human somatic cells differ from those factors that can reprogram somatic cells from model organisms (including mice) because ES cells from mice and humans require distinct sets of factors to remain undifferentiated, illustrating the significance of species-specific differences, even among mammals. For example, the leukemia inhibitory factor (LIF)/Stat3 pathway, a key to mouse ES cell proliferation, does not support human ES cell proliferation and appears inactive in conditions that support human ES cells (Daheron L, et al., Stem Cells 22:770-778 (2004); Humphrey R, et al., Stem Cells 22:522-530 (2004); and Matsuda T, et al., EMBO J. 18:4261-4269 (1999)).

Similarly, while bone morphogenetic proteins (BMPs) together with LIF support mouse ES cell self-renewal at clonal densities in serum-free medium (Ying Q, et al., Cell 115:281-292 (2003)), they cause rapid human ES cell differentiation in conditions that would otherwise support self-renewal, such as culture on fibroblasts or in fibroblast-conditioned medium (Xu R, et al., Nat. Biotechnol. 20:1261-1264 (2002)). Indeed, inhibition of BMP signaling in human ES cells is beneficial (Xu R, et al., Nat. Methods 2:185-190 (2005)).

Still further, fibroblast growth factor (FGF) signaling is important to self-renewal of human ES cells, but apparently not for mice (Xu et al., (2005), supra; and Xu C, et al., Stem Cells 23:315-323 (2005)).

Accordingly, the art still seeks a set of potency-determining factors suited at least for use in methods for reprogramming primate (including human and non-human) somatic cells to yield pluripotent cells. Such cells, obtained without relying upon embryonic tissues, would be suited for use in applications already contemplated for existing, pluripotent, primate ES cells.

#### BRIEF SUMMARY

The present invention is broadly summarized as relating to methods for reprogramming differentiated, somatic, primate cells into pluripotent cells, and more specifically into iPS cells. As used herein, "iPS cells" refer to cells that are substantially genetically identical to their respective differentiated somatic cell of origin and display characteristics similar to higher potency cells, such as ES cells, as described 5 herein. The cells can be obtained from various differentiated (i.e., non-pluripotent and multipotent) somatic cells.

iPS cells exhibit morphological (i.e., round shape, large nucleoli and scant cytoplasm) and growth properties (i.e., doubling time; ES cells have a doubling time of about 10 seventeen to eighteen hours) akin to ES cells. In addition, iPS cells express pluripotent cell-specific markers (e.g., Oct-4, SSEA-3, SSEA-4, Tra-1-60, Tra-1-81, but not SSEA-1). iPS cells, however, are not immediately derived from embryos and can transiently or stably express one or more 15 copies of selected potency-determining factors at least until they become pluripotent. As used herein, "not immediately derived from embryos" means that the starting cell type for producing iPS cells is a non-pluripotent cell, such as a multipotent cell or terminally differentiated cell, such as 20 somatic cells obtained from a post-natal individual.

In the methods described herein, at least two potencydetermining factors can be introduced into, and expressed in, differentiated somatic cells, whereupon the somatic cells convert in culture to cells having properties characteristic of 25 pluripotent cells, such as human ES cells (i.e., express at least Oct-4, SSEA-3, SSEA-4, TRA-1-60 or TRA-1-81, but not SSEA-1, and appear as compact colonies having a high nucleus to cytoplasm ratio and prominent nucleolus), that can differentiate into cells characteristic of all three germ 30 layers, and that contain the genetic complement of the somatic cells of a post-natal individual. Apart from genetic material introduced to encode the potency-determining factors, the reprogrammed (i.e., converted) cells are substantially genetically identical to the somatic cells from which 35 promoter into which a knock-in construct was introduced. In they were derived.

As used herein, a "potency-determining factor" refers to a factor, such as a gene or other nucleic acid, or a functional fragment thereof, as well as an encoded factor or functional fragment thereof, used to increase the potency of a somatic 40 cell, so that it becomes pluripotent. The potency-determining factors optionally can be present only transiently in the reprogrammed cells or can be maintained in a transcriptionally active or inactive state in the genome of the reprogrammed cells. Likewise, the potency-determining factors 45 can be present in more than one copy in the reprogrammed cells, where the potency-determining factor can be integrated in the cell's genome, can be extra-chromosomal or both. The potency-determining factors can include, but are not limited to, Stella (SEQ ID NO:1); POU5F1 (Oct-4; SEQ 50 construct of FIG. 1. ID NO:2), Sox2 (SEQ ID NO:3), FoxD3, UTF1, Rex1, ZNF206, Sox15, Myb12, Lin28 (SEQ ID NO:4), Nanog (SEQ ID NO:5), DPPA2, ESG1, Otx2 and subsets thereof. In some embodiments, as few as two potency-determining factors, e.g., Oct-4 and Sox2, can be sufficient. Efficiency in 55 obtaining reprogrammed cells, however, can be improved by including additional potency-determining factor, such as Lin28, Nanog or both.

In a first aspect, the invention relates to a replenishable, enriched population of pluripotent cells obtained from a 60 post-natal individual, especially from a living individual, but optionally from a deceased individual. Cells in the enriched cell population express at least one cell-type-specific marker, including, but not limited to, Oct-4, SSEA3, SSEA4, Tra-1-60, Tra-1-81 or combinations thereof and have other 65 hallmarks of pluripotent cells, such as ES cells. In addition, the pluripotent cells may express alkaline phosphatase

4

(ALP). Furthermore, the pluripotent cells may have a genome substantially genetically identical to that of a preexisting, differentiated cell from the individual. Likewise, the pluripotent cells may have a genome that encodes at least one of the potency-determining factors, which may be transcriptionally active or inactive after reprogramming. Additionally, the potency-determining factors may be in a form of a reprogramming sequence in which a polynucleotide encoding the potency-determining factor is operably linked to a heterologous promoter. As used herein, "heterologous promoter" means a promoter that is operably linked to a polynucleotide for which the promoter does not normally initiate transcription.

In a second aspect, the invention relates to methods and compositions for identifying potency-determining factors required to reprogram somatic cells into pluripotent cells.

Unless otherwise defined, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although suitable methods and materials for the practice or testing of the present invention are described below, other methods and materials similar or equivalent to those described herein, which are well known in the art, can also be used.

Other objects, advantages and features of the present invention will become apparent from the following specification taken in conjunction with the accompanying drawings

#### BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

FIG. 1 illustrates a site downstream from a human Oct4 cells containing the knock-in construct, enhanced green fluorescent protein (EGFP) and neomycin phosphotransferase (NEO) are expressed when the Oct4 promoter is active. These cells can be used to evaluate which factors can reprogram somatic cells into pluripotent cells.

FIGS. 2A-B illustrate human H1 ES cell differentiation. FIG. 2A shows schematics of myeloid precursor derivation and purification from human ES cells. FIG. 2B shows phenotypic analysis of differentiated cells obtained after Percoll® separation. Gray line: isotype control; black line: antibody staining Abbreviations: hESC, human embryonic stem cell; MPO, myeloperoxidase; pHEMA, poly(2-hydroxyethyl methacrylate).

FIG. 3 illustrates the Oct-4 region containing the knock-in

FIGS. 4A-C illustrate lentiviral transduction of somatic cells. FIG. 4A shows a schematic diagram of lentiviral construct. FIG. 4B shows Percoll®-purified cells were transduced with EGFP-expressing lentiviral vectors at various MOI. EGFP expression was analyzed by flow cytometry three days after transduction without drug selection. FIG. 4C shows lentiviral transduction of Percoll®-purified cells after several additional days of culture on Matrigel®. EGFP expression was analyzed two days after lentiviral transduction.

FIG. 5 illustrates transgene overexpression in cells differentiated for seven days on Matrigel®. No significant change in morphology was observed in cells overexpressing Nanog or EGFP (control). Morphology of Oct-4-expressing cells changes dramatically, and many of these cells survived neomycin selection, but none of these cells showed typical human ES cell morphology, indicating that a drug-selectable

population of Oct-4-expressing ES cells does not persist through the culture period necessary for myeloid differentiation.

FIGS. **6**A-B illustrate reprogramming of Oct4KICD45+A cells through introduction of fourteen potency-determining factors. FIG. **6**A shows the established clones display undifferentiated human ES cell morphology and express EGFP under direction of the endogenous Oct4 promoter. FIG. **6**B shows flow cytometry analysis of human ES cell-specific cell surface antigen expression in established clones. Gray line: isotype control; black line: antibody staining.

FIGS. 7A-C illustrate reprogramming efficiency, as evidenced by colony formation, after introduction of various sets of potency-determining factors. FIG. 7A shows the identified set of fourteen potency-determining factors was introduced into cells in combinations, wherein each combination excluded one of the fourteen factors. By evaluating the ability of the potency-determining factors to reprogram the tested cells to an ES-like state, the inventors determined whether the excluded potency-determining factor was essential to the reprogramming. For example, a set of potency- 20 determining factors termed M1 that lacked Oct-4 (depicted as M1-Oct-4) was unable to form a significant number of ES-like colonies. As such, it was concluded that Oct-4 was important for somatic cell reprogramming. FIG. 7B shows a set of potency-determining factors (narrowed from FIG. 7A) evaluated for further testing was narrowed from fourteen to four (M4, being Oct-4, Sox2, Lin28 and Nanog). These four potency-determining factors were tested by serially excluding one of the four from the combination. Where a combination of three potency-determining factors (e.g., M4 Oct. 4) was unable to reprogram the tested cells to form a significant number of stable ES-like colonies, the inventors concluded that the omitted gene is important for somatic cell reprogramming. In FIG. 7B, the light gray bars indicate the total number of reprogrammed colonies formed having typical human ES cell morphology; dark gray bars indicate the 35 number of large colonies with minimal differentiation. FIG. 7C shows a set of potency-determining factors (narrowed from FIG. 7B) evaluated for further testing was narrowed from four to two (i.e., Oct-4 and Sox2). Oct-4, Sox2, Lin28 and Nanog were tested by serially excluding two of the four 40 from the combination.

FIGS. **8**A-B illustrate reprogramming in human adult skin fibroblasts. FIG. **8**A shows bright-field images of human adult skin cell (p5) (left) and reprogrammed cells (right). FIG. **8**B shows flow cytometry analysis of human ES <sup>45</sup> cell-specific markers in human adult skin cells (p5) (bottom) and reprogrammed cells (top). Gray line: isotype control; black line: antibody staining.

FIGS. **9**A-B illustrate the effect on reprogramming of relative expression of Oct-4 and Sox2. FIG. **9**A shows <sup>50</sup> Western blot analysis of Oct-4 and Sox2 in 293FT cells; lane 1, pSin4-EF2-Oct4-IRES1-Sox2 (OS-IRES1); lane 2, pSin4-EF2-Oct4-IRES2-Sox2 (OS-IRES2); lane 3, pSin4-EF2-Oct4-F2A-Sox2 (OS-F2A); lane 4, pSin4-EF2-Oct4-IRES1-puro (O); lane 5, pSin4-EF2-Sox2-IRES1-puro (S); <sup>55</sup> lane 6, no plasmid (control). FIG. **9**B shows reprogramming in mesenchymal cells derived from OCT4 knock-in human ES cells using linked potency-determining factors; gene combinations are the same as in FIG. **9**A, with the addition of pSin4-EF2-Nanog-IRES1-puro (N) and pSin4-EF2- <sup>60</sup> Lin28-IRES1-puro (L).

#### DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS

The inventors hypothesized that potency-determining factors present in primate ES cells play an important role in

65

6

maintaining pluripotency and that differentiated somatic cells could be reprogrammed to a state of pluripotency through expression of potency-determining factors.

Cell types pass through various levels of potency during differentiation, such as totipotency, pluripotency and multipotency. Of particular interest herein are pluripotent cells. As used herein, "pluripotent cells" refer to a population of cells that can differentiate into all three germ layers (e.g., endoderm, mesoderm and ectoderm). Pluripotent cells express a variety of pluripotent cell-specific markers, have a cell morphology characteristic of undifferentiated cells (i.e., compact colony, high nucleus to cytoplasm ratio and prominent nucleolus) and form teratomas when introduced into an immunocompromised animal, such as a SCID mouse. The teratomas typically contain cells or tissues characteristic of all three germ layers. One of ordinary skill in the art can assess these characteristics by using techniques commonly used in the art. See, e.g., Thomson et al., supra. Pluripotent cells are capable of both proliferation in cell culture and differentiation towards a variety of lineage-restricted cell populations that exhibit multipotent properties. Multipotent somatic cells are more differentiated relative to pluripotent cells, but are not terminally differentiated. Pluripotent cells therefore have a higher potency than multipotent cells. As used herein, "reprogrammed pluripotent primate stem cells" (and similar references) refer to the pluripotent products of somatic cell reprogramming methods. Such cells are suitable for use in research and therapeutic applications currently envisioned for human ES cells.

The present invention broadly relates to novel methods for reprogramming differentiated somatic cells into higherpotency cells, such as pluripotent cells, by administering at least two potency-determining factors into somatic cells to achieve a higher level of potency in the reprogrammed cells than in the somatic cells. Advantageously, the present invention allows the generation of pluripotent cells, such as iPS cells, from somatic cells without requiring an addition of cell surface receptors for introducing the potency-determining factors to the somatic cells. As used herein, "reprogramming" refers to a genetic process whereby differentiated somatic cells are converted into de-differentiated, pluripotent cells, and thus have a greater pluripotency potential than the cells from which they were derived. That is, the reprogrammed cells express at least one of the following pluripotent cell-specific markers: SSEA-3, SSEA-4, TRA-1-60 or TRA 1-81. Preferably, the reprogrammed cells express all these markers.

Potency-determining factors that can reprogram somatic cells include, but are not limited to, factors such as Oct-4, Sox2, FoxD3, UTF1, Stella, Rex1, ZNF206, Sox15, Myb12, Lin28, Nanog, DPPA2, ESG1, Otx2 or combinations thereof. In the examples, a set with as few as two of the fourteen factors was sufficient to reprogram the tested cells; this set included Oct-4 and Sox2. Addition of other potency-determining factors to Oct-4 and Sox2, however, increased the efficiency with which reprogrammed cells were obtained. c-Myc and Klf4, however, are not essential as potency-determining factors. Preferably, the potency-determining factor may be a transcription factor.

Suitable somatic cells can be any somatic cell, although higher reprogramming frequencies are observed when the starting somatic cells have a doubling time about twentyfour hours. Somatic cells useful in the invention are nonembryonic cells obtained from a fetal, newborn, juvenile or adult primate, including a human. Examples of somatic cells that can be used with the methods described herein include, but are not limited to, bone marrow cells, epithelial cells, fibroblast cells, hematopoietic cells, hepatic cells, intestinal cells, mesenchymal cells, myeloid precursor cells and spleen cells. Another type of somatic cell is a CD29<sup>+</sup> CD44<sup>+</sup> CD166<sup>+</sup> CD105<sup>+</sup> CD73<sup>+</sup> and CD31<sup>-</sup> mesenchymal cell that attaches to a substrate. Alternatively, the somatic cells can be 5 cells that can themselves proliferate and differentiate into other types of cells, including blood stem cells, muscle/bone stem cells, brain stem cells and liver stem cells. Multipotent hematopoietic cells, suitably myeloid precursor or mesenchymal cells, are specifically contemplated as suited for use 10 in the methods of the invention.

Likewise, suitable somatic cells are receptive, or can be made receptive using methods generally known in the scientific literature, to uptake of potency-determining factors including genetic material encoding the factors. Uptake- 15 enhancing methods can vary depending on the cell type and expression system. Exemplary conditions used to prepare receptive somatic cells having suitable transduction efficiency are known in the art and are described in the examples below. One method for making cells receptive to 20 potency-determining factors is described below in connection with the electroporation methods.

A potency-determining factor may be introduced as a reprogramming sequence in which a polynucleotide sequence encoding the potency-determining factor is oper-25 ably linked to a heterologous promoter, which may become inactive after somatic cells are reprogrammed. The heterologous promoter is any promoter sequence that can drive expression of a polynucleotide sequence encoding the potency-determining factor in the somatic cell, such as, e.g., 30 an Oct4 promoter.

The relative ratio of potency-determining factors may be adjusted to increase reprogramming efficiency. For example, linking Oct-4 and Sox2 in a 1:1 ratio on a single vector increased reprogramming efficiency in cells by a factor of 35 four (FIG. **9**A-B) when compared to reprogramming efficiency wherein the potency-determining factors were provided to cells in separate constructs and vectors, where the uptake ratio of the respective potency-determining factors into single cells was uncontrolled. Although the ratio of 40 potency-determining factors used, one of ordinary skill in possession of this disclosure can readily determine an optimal ratio of potency-determining factors.

Pluripotent cells can be cultured in any medium used to 45 support growth of pluripotent cells. Typical culture medium includes, but is not limited to, a defined medium, such as TeSR<sup>™</sup> (StemCell Technologies, Inc.; Vancouver, Canada), mTeSRTM (StemCell Technologies, Inc.) and StemLine  $\ensuremath{\mathbb{R}}$ serum-free medium (Sigma; St. Louis, Mo.), as well as 50 conditioned medium, such as mouse embryonic fibroblast (MEF)-conditioned medium. As used herein, a "defined medium" refers to a biochemically defined formulation comprised solely of biochemically-defined constituents. A defined medium may also include solely constituents having 55 known chemical compositions. A defined medium may further include constituents derived from known sources. As used herein, "conditioned medium" refers to a growth medium that is further supplemented with soluble factors from cells cultured in the medium. Alternatively, cells can be 60 maintained on MEFs in culture medium.

The inventors used a serial analysis of gene expression (SAGE) library to obtain transcriptome profiles of genes abundant in ES cells. Specifically, a SAGE library was used to identify potency-determining factors that regulate pluri-65 potency and self-renewal in ES cells. SAGE libraries are well-known to one of ordinary skill in the art and are

publicly available or can be specifically constructed by companies, such as Agencourt Bioscience Corp. (Beverly, Mass.).

In another aspect, the invention provides an enriched population of pluripotent cells substantially genetically identical to cells of a post-natal individual. The cells can be obtained by reprogramming somatic cells isolated from the post-natal individual. In some embodiments, the cell population is a purified population, representing at least 60%, 70%, 80% and advantageously greater than 95% of the cells in the population, and any and all whole or partial integers therebetween. The reprogrammed cells are euploid, exhibit cell morphology characteristic of pluripotent cells and express pluripotent cell-specific markers, such as, e.g., Oct-4, SSEA-3, SSEA-4, Tra-1-60, Tra-1-81 or combinations thereof, and form teratomas when introduced into an immunocompromised animal.

Yet another aspect provides methods and compositions for identifying and using potency-determining factors sufficient to reprogram somatic cells into pluripotent cells. As noted herein, the reprogrammed pluripotent cells contain the genetic complement of, and are substantially genetically identical to somatic cells obtained from a post-natal individual. Generally, methods for identifying potency-determining factors include the steps of introducing genetic material encoding one or a plurality of putative potencydetermining factors into somatic cells receptive to uptake of the genetic material under conditions effective to express the factors encoded on the introduced genetic material at levels sufficient to reprogram the cells to a less differentiated, higher-potency state; and observing a population of pluripotent cells after introduction of the genetic material. The pluripotent cells can be characterized by cell morphology, pluripotent cell-specific markers or both. Advantageously, the pluripotent cells can be identified by expression in the treated cells of a marker provided in the cells so as to be expressed only upon reprogramming of the cells to a pluripotent state. Through this approach, potency-determining factors capable of reprogramming somatic cells into pluripotent cells can be identified, as is described in the examples below.

Genetic material encoding a potency-determining factor can be introduced by transfection or transduction into the somatic cells using a vector, such as an integrating- or non-integrating vector. Of particular interest herein are retroviral vectors. Retroviral vectors, particularly lentiviral vectors, are transduced by packaging the vectors into virions prior to contact with a cell. After introduction, the DNA segment(s) encoding the potency-determining factor(s) can be located extra-chromosomally (e.g., on an episomal plasmid) or stably integrated into cellular chromosome(s).

A viral-based gene transfer and expression vector is a genetic construct that enables efficient and robust delivery of genetic material to most cell types, including non-dividing and hard-to-transfect cells (primary, blood, stem cells) in vitro or in vivo. Viral-based constructs integrated into genomic DNA result in high expression levels. In addition to a DNA segment that encodes a potency-determining factor of interest, the vectors include a transcription promoter and a polyadenylation signal operatively linked, upstream and downstream, respectively, to the DNA segment. The vector can include a single DNA segment encoding a single potency-determining factor or a plurality of potency-determining factor-encoding DNA segments. A plurality of vectors can be introduced into a single somatic cell. The vector can optionally encode a selectable marker to identify cells that have taken up and express the vector. As an example,

when the vector confers antibiotic resistance on the cells, antibiotic can be added to the culture medium to identify successful introduction of the vector into the cells. Integrating vectors can be employed, as in the examples, to demonstrate proof of concept. Retroviral (e.g., lentiviral) vectors 5 are integrating vectors; however, non-integrating vectors can also be used. Such vectors can be lost from cells by dilution after reprogramming, as desired. A suitable nonintegrating vector is an Epstein-Barr virus (EBV) vector. Ren C, et al., Acta. Biochim. Biophys. Sin. 37:68-73 (2005); 10 and Ren C, et al., Stem Cells 24:1338-1347 (2006), each of which is incorporated herein by reference as if set forth in its entirety.

The vectors described herein can be constructed and engineered using art-recognized techniques to increase their 15 safety for use in therapy and to include suitable expression elements and therapeutic genes. Standard techniques for the construction of expression vectors suitable for use in the present invention are well-known to one of ordinary skill in the art and can be found in such publications such as 20 Sambrook J, et al., "Molecular cloning: a laboratory manual," (3rd ed. Cold Spring Harbor Press, Cold Spring Harbor, N.Y. 2001), incorporated herein by reference as if set forth in its entirety.

The ability to identify and enrich for pluripotent cells can 25 be facilitated by providing a non-lethal marker in the somatic cells, such as Green Fluorescent Protein (GFP), Enhanced Green Fluorescent Protein (EGFP) or luciferase, under the control of a promoter active only after the somatic cell has converted to a pluripotent state. A selectable marker 30 gene is used to identify the reprogrammed cells expressing the marker through visible cell selection techniques, such as fluorescent cell sorting techniques. Alternatively, the reprogrammed cells can be produced without a selectable marker. In the examples below, a marker was provided in the 35 genome of the somatic cells downstream of the promoter that regulates Oct-4 expression. The endogenous Oct4 promoter is active in undifferentiated, pluripotent ES cells. A drug-selectable population of Oct-4-expressing ES cells did not persist through the culture period necessary for myeloid 40 cells were transduced with polynucleotides encoding differentiation. However, because some Oct-4 expression can persist into early stages of differentiation, it is appropriate to enrich the population for pluripotent cells by selecting colonies having characteristic ES cell morphology and by maintaining the cells under ES cell maintenance 45 culture conditions. It is not intended that all cells in the reprogrammed cell culture have the desired level of potency. Given the inefficiencies of cell sorting technology, the variations in levels of gene expression and other biological effects, some cells in the enriched population may not be 50 pluripotent. However, at a practical level, the reprogrammed cell population derived from somatic cells is enriched for pluripotent cells.

The non-lethal marker can be constructed to enable its subsequent removal using any of a variety of art-recognized 55 techniques, such as removal via Cre-mediated, site-specific gene excision. For example, it may become desirable to delete the marker gene after the pluripotent cell population is obtained, to avoid interference by the marker gene product in the experiment or process to be performed with the cells. 60 Targeted deletions can be accomplished by providing structure(s) near the marker gene that permits its ready excision. That is, a Cre/Lox genetic element can be used. The Lox sites can be built into the cells. If it is desired to remove the marker from the pluripotent cells, the Cre agent can be 65 added to the cells. Other similar systems also can be used. Because Cre/Lox excision can introduce undesirable chro-

mosomal rearrangements and can leave residual genetic material after excision, the inventors recognize the desirability of introducing the potency-determining factors into the somatic cells using non-integrating, episomal vectors and obtaining cells from which the episomal vectors are lost (e.g., at a rate of about 5% per generation) by subsequently withdrawing the drug selection used to maintain the vectors during the reprogramming step.

The following examples are provided as further nonlimiting illustrations of methods for identifying potencydetermining genes or factors for converting somatic cells into pluripotent cells. In some examples, human H1 Oct4 knock-in ES cells were differentiated in stromal cell coculture to yield cells suited for use as reprogrammable somatic cells. These cells are a model for cells isolated from a post-natal individual for use in a somatic cell reprogramming method.

The methods were repeated with other differentiated cell types. One cell type was human fetal lung fibroblast cells, IMR-90. See, Nichols W, et al., Science 196:60-63 (1977), incorporated herein by reference as if set forth in its entirety. IMR-90 cells are being extensively characterized by the ENCODE Consortium, are readily available from American Type Culture Collection (ATCC; Manassas, Va.; Catalog No. CCL-186), and have published DNA fingerprints that allow independent confirmation of the origin of reprogrammed clones. In addition, these cells proliferate robustly in Eagle's Minimal Essential Medium-10% FBS for more than twenty passages before undergoing senescence, but grow slowly in human ES cell culture conditions, a difference that provides a proliferative advantage to reprogrammed clones and aids in their selection by morphological criteria alone. Other differentiated cell types used in the methods were human post-natal foreskin fibroblast cells (ATCC; Catalog No. CRL-2097) and human adult skin cells (ATCC; Catalog No. CRL-2106).

The cells were made receptive for transduction with a viral expression system as described below. The somatic potency-determining factors thought to be associated with pluripotency, such that the somatic cells were reprogrammed to pluripotent cells. It is not yet determined whether all fourteen potency-determining factors provided in transduction vectors were taken up and expressed in the somatic cells. Having identified a set of fourteen potency-determining factors, and a subset of at least two of the fourteen factors, sufficient to reprogram somatic cells, the inventors provide one of ordinary skill in art the with the ability to identify one or more specific subsets of the potency-determining factors that are also capable of somatic reprogramming, thereby facilitating identification of other subsets of such potency-determining factors. Accordingly, the methods described below facilitate the identification of the potencydetermining factors involved in reprogramming somatic cells into pluripotent cells.

It is specifically envisioned that the set of potencydetermining factors sufficient to reprogram somatic cells can vary with the cell type of the somatic cells. It is noted that exposure to a set of fourteen potency-determining factors resulted in conversion to a pluripotent status in cultures of the indicated somatic cells. As shown below, one can identify a set of potency-determining factors sufficient to reprogram other cell types by repeating the methods described below using different combinations of potency-determining factors, which may include some or all of the fourteen factors as well as other potency-determining factors. Con-

sequently, one can produce pluripotent cell lines/populations that are substantially genetically identical to a pre-existing, differentiated, somatic cell.

#### EXAMPLES

In the following examples, differentiated cells received vectors that encoded various potency-determining factors. Some of the cells contained in their genome a marker gene that encodes EGFP positioned downstream from the regu-<sup>10</sup> lated Oct4 promoter, which is active only in pluripotent cells. The production of this useful tool is described in Yu et al., supra, which demonstrated that differentiated cells can become pluripotent via cell-cell fusion with human ES cells.

#### Example 1

#### Lentiviral Vector Packaging and Production

Transgene-expressing lentivirus vector was produced in 293FT cell lines (Invitrogen). 293T is a fast-growing, highly transfectable clonal variant derived from transformed 293 embryonal kidney cells, which contains the large T antigen for high-level expression of the packaging proteins that contribute to higher viral titers. For routine maintenance and expansion, these cells were cultured in 293FT medium (DMEM/10% FBS, 2 mM L-glutamine and 0.1 mM MEM Non-Essential Amino Acids) in the presence of 500 µg/ml geneticin. For packaging, 293FT cells were collected by 30 trypsinization. Following removal of trypsin by centrifugation, these cells were aliquoted into T75 flasks (15×10<sup>6</sup> cells/flask, and 6 flasks per construct) in 293FT medium without geneticin.

Co-transfection of lentiviral vector and two helper plas- 35 mids was carried out with Superfect® transfection reagent (Qiagen) immediately following cell aliquoting (lentiviral vector:MD.G:pCMVdeltaR8.9:Superfect®=5 µg:5 µg:10 μg:40 μl in 400 μl of Iscove's Modified Dulbecco's Medium (IMDM)  $(1\times)$ /flask incubated at room temperature for 10 40 minutes). The next day, the culture medium containing the transfection mixture was replaced with fresh 293FT medium supplemented with 1 mM sodium pyruvate (8 ml/flask). Lentivirus-containing supernatant was collected around 48 to 72 hours after transduction (~48 ml per construct). The 45 293FT cell debris was removed from the supernatant by centrifugation at 3000 rpm (1750 g) for 15 minutes at 4° C. To concentrate the lentivirus, the supernatant was filtered through 0.4 µM cellulose acetate (CA) membrane (Cornington, 115 ml low-protein binding), and ultracentrifuged in 70 50 ml sterilized bottles (Beckman, Cat#355622, polycarbonate for 45Ti rotor only) at 33,000 rpm (50,000 g) for 2.5 hours at 4° C. Lentivirus along with any remaining cell debris formed a visible pellet at the bottom of the centrifuge tube. Following supernatant removal, PBS (~300 µl for each 55 construct) was added to resuspend the pellet by rocking the centrifuge tubes at 4° C. for 8 to 14 hours, or at room temperature for 2 hours. The remaining cell debris was removed by centrifugation at 5000 rpm (2700 g) for 5 minutes, and the resuspended lentivirus was aliquoted and 60 stored at  $\sim 80^{\circ}$  C. The titer obtained generally ranged between  $10^7$  to  $10^8$  viral particles (vp)/ml after concentration. The sequence for a lentivirus (pSIN4-EF2-Stella-puro; SEQ ID NO:6, with the sequence for Stella from 3604 to 4083) harboring Stella (SEQ ID NO:1) is provided in the 65 Sequence Listing. The same sequence was used for all other potency-determining factors (e.g., SEQ ID NOS: 2-5),

except that the sequence for Stella (SEQ ID NO:1) was replaced with the sequence of another potency-determining factor.

To efficiently introduce potency-determining factors into myeloid cells, inventors modified the lentiviral expression system (FIG. **4**A). Inventors reduced the size of the original lentiviral construct (>11 kb) by removing sequences neighboring 5' and 3' LTRs through serial deletion analysis. These modifications minimized the negative effect on the packaging efficiency. The titer obtained routinely ranged between  $10^5$  to  $10^6$  vp/ml of supernatant, and  $10^7$  to  $10^8$  vp/ml after concentration (through ultracentrifugation). Restriction sites were introduced into the backbone for convenient exchanges of the coding regions for specific transgenes.

#### Example 2

#### Reprogramming of Myeloid Precursor Cells after Lentiviral Transduction and Expression of Potency-determining Factors

To identify genes capable of reprogramming differentiated cells back to a state of pluripotency, efficient transduction of the cells is required. Inventors first tested the lentiviral transduction efficiency immediately after Percoll® purification of a human H1 Oct4 knock-in ES cells (FIG. 2).

H1.1 human ES cells (WiCell Research Institute; Madison, Wis.) were maintained on irradiated mouse embryonic fibroblasts (MEFs) in DMEM/F12 culture medium consisting of 80% Dulbecco's modified Eagle's medium (no pyruvate, high glucose formulation; Invitrogen; Carlsbad, Calif.) supplemented with 20% KnockOut serum replacer, 1% non-essential amino acids (Gibco), 1 mM L-glutamine, 0.1 mM β-mercaptoethanol (Sigma) and 4 ng/ml basic fibroblast growth factor (bFGF) (all from Invitrogen unless otherwise noted), as previously described (see Amit et al., Dev Biol. 227:271-278 (2000); and Thomson et al., Science 282:1145-1147 (1998), each of which is incorporated herein by reference as if set forth in its entirety). Feeder-free culture on Matrigel® (BD Biosciences; Bedford, Mass.) with chemically defined TeSR<sup>™</sup> medium (StemCell Technologies, Inc.) was carried out as described in Ludwig et al. Ludwig T, et al, Nat. Methods. 3:637-646 (2006); and Ludwig T, et al., Nat. Biotechnol. 24:185-187 (2006), each of which is incorporated herein by reference as if set forth in its entirety.

The H1 Oct4 knock-in ES cell line was generated from the H1.1 human ES cells according to a method described by Zwaka & Thomson. U.S. Patent Publication No. 2006/ 0128018 and Zwaka T & Thomson J, Nat. Biotechnol. 21:319-321 (2003), each of which is incorporated herein by reference as if set forth in its entirety. Briefly, a gene targeting vector was constructed by inserting a cassette, an IRES-EGFP, an IRES-NEO and a simian virus polyadenylation sequence (approximately 3.2 kilobases (kb)) into the 3' untranslated region of the fifth exon of the human Oct-4 (octamer-binding transcription factor 4) gene, also known as POU domain, class 5, transcription factor 1 (POU5F1). This cassette was flanked in the 5' direction by a 6.3 kb homologous arm and by a 1.6 kb (6.5 kb in the alternative targeting vector) homologous arm in the 3' region (FIG. 1). The cassette was inserted at position 31392 of the Oct-4 gene (SEQ ID NO:2). The long arm contained a sequence from 25054-31392. The short arm contained a sequence from 31392-32970. In an alternative targeting vector, the short arm was substituted by a longer homologous region (31392-32970 in AC006047 plus 2387-7337 in gene accession number AC004195). Isogenic homologous

DNA was obtained by long-distance, genomic PCR and subcloned. All genomic fragments and the cassette were cloned into the multiple cloning site (MCS) of a cloning vector, pBluescript® SK II (GenBank Accession Number X52328; Stratagene; La Jolla, Calif.).

For electroporation, cells were harvested with collagenase IV (1 mg/ml, Invitrogen) for 7 minutes at 37° C., washed with medium and re-suspended in 0.5 ml culture medium  $(1.5-3.0\times10^7 \text{ cells})$ . To prepare the cells for electroporation, cells were added to 0.3 ml phosphate-buffered saline (PBS; 10 Invitrogen) containing 40 mg linearized targeting vector DNA. Cells were then exposed to a single 320 V, 200 µF pulse at room temperature using a BioRad Gene Pulser® II (0.4 cm gap cuvette). Cells were incubated for ten minutes at room temperature and were plated at high-density on 15 Matrigel®. G418 selection (50 mg/ml; Invitrogen) was started 48 hours after electroporation. After one week, G418 concentration was doubled. After three weeks, surviving colonies were analyzed individually by PCR using primers specific for the NEO cassette and for the POU5F1 gene just 20 downstream of 3' homologous region, respectively. PCRpositive clones were re-screened by Southern blot analysis using BamHI digested DNA and a probe outside the targeting construct.

The H1 Oct4 knock-in ES cell line expressed both EGFP 25 and neomycin phosphotransferase (neo) from an endogenous Oct4 promoter/regulatory region using dual internal ribosome-entry sites (IRES) (FIG. **3**). Expression of EGFP and neo in the H1 Oct4 knock-in ES cells indicated an active, endogenous Oct4 promoter/regulatory region. 30

H1 Oct4 knock-in ES cells were maintained through co-culture with mouse OP9 bone marrow stromal cells (FIG. 2A) maintained on gelatin-coated 10 cm plastic dishes (BD Biosciences) consisting of: DMEM medium (Invitrogen) supplemented with 20% non-heat-inactivated defined fetal 35 bovine serum (FBS; HyClone Laboratories; Logan, Utah) (10 ml/dish). The OP9 cultures were split every 4 days at a ratio of 1:7. For use in human ES cell differentiation, after OP9 cells reached confluence on the fourth day, half of the medium was changed, and the cells were cultured for an 40 additional four days.

For reprogramming, H1 Oct4 knock-in ES cells were differentiated into attached cells (i.e., CD29+CD44+ CD166+CD105+CD73+CD31-). Briefly, human H1 Oct4 knock-in ES cells (p76 to 110) were added to the OP9 45 monolayer (1.5×10<sup>6</sup>/10-cm dish) in 20 ml of DMEM medium supplemented with 10% FBS (HvClone Laboratories) and 100 µM monothioglycerol (MTG; Sigma; St. Louis, Mo.). The human ES/OP9 cell co-culture was incubated for nine days with changes of half of the medium on 50 days 4, 6 and 8. After incubation, the co-culture was dispersed into individual cells by collagenase IV treatment (1 mg/ml in DMEM medium, Invitrogen) for 20 minutes at 37° C., followed by trypsin treatment (0.05% Trypsin/0.5 mM EDTA, Invitrogen) for 15 minutes at 37° C. Cells were 55 washed twice with medium and re-suspended at  $2 \times 10^6$ /ml in DMEM medium supplemented with 10% FBS, 100 µM MTG and 100 ng/ml GM-CSF (Leukine; Berlex Laboratories Inc.; Richmond, Calif.). Cells were further cultured in flasks coated with poly (2-hydroxyethyl methacrylate) 60 (pHEMA; Sigma) for 10 days with changes of half of the medium every 3 days. During adhesion-preventing pHEMA culture, cells that would otherwise be adherent formed floating aggregates, while the cells of interest grew as individual cells in suspension. Large cell aggregates were 65 removed by filtration through 100 µM cell strainers (BD Biosciences), while small aggregates and dead cells were

removed by centrifugation through 25% Percoll® (Sigma). The differentiated cells recovered from the cell pellet expressed CD33, MPO, CD11b and CD11c molecules, which are characteristic for bone marrow myeloid cells (FIG. 2B). Inventors routinely produce  $6-10\times10^6$  differentiated cells from  $1\times10^6$  H1 ES cells (human H1 Oct4 knock-in ES cells). See also, Yu J, et al., Science 318:1917-1920 (2007), including the supplemental materials available at the Science website on the World Wide Web, incorporated herein by reference as if set forth in its entirety.

Lentivirus encoding a potency-determining factor (MOI: 3 to 10) was added to the cell culture after addition of polybrene carrier at a final concentration of  $6 \mu g/ml$  (Sigma). The lentivirus-containing medium was replaced with fresh medium the next day, and cells were cultured further in appropriate medium. Drug selection, if needed, started the third day after transduction. As shown in FIG. **5**B, the transduction efficiency was very low (~18.4% at MOI of 10). Moreover, the expression of EGFP was barely above background. Similar results have been obtained with routine plasmid or Epstein-Barr virus nuclear antigen (EBNA)-based plasmid transfections (data not shown).

On the other hand, cells having high transduction efficiency were prepared as follows. The Percoll®-purified H1 Oct4 knock-in ES cells were allowed to differentiate further to mesenchymal-like cells for an additional seven days in the presence of GM-CSF on Matrigel®, as described above. Many cells attached to the plate during this culture period. The attached cells (referred to herein below as Oct4KICD45+A cells, or simply as CD45+A cells) showed significantly higher transduction efficiency (FIG. 4C) and were used for this reprogramming experiment. While the cells were not CD45 at the time of the experiments, the cells were obtained from CD45 cells. As noted elsewhere herein, cell surface markers on the attached cells were characterized as CD29<sup>+</sup>, CD44<sup>+</sup>, CD166<sup>+</sup>, CD105<sup>+</sup>, CD73<sup>+</sup> and CD31<sup>-</sup>.

Inventors tested the hypothesis that differentiated cells could be reprogrammed to a state of pluripotency by expressing potency-determining factors in Oct4KICD45+A cells (FIG. 3), and obtained promising results. Because Nanog and Oct-4 are the best characterized potency-determining factors, inventors examined the effect of their over-expression in the cells.

The Oct4KICD45+A cells were first dissociated to individual cells with trypsin and replated onto Matrigel® at  $\sim 10^5$ cells/well of 6-well plates in TeSR<sup>™</sup> medium. Transgeneexpressing lentiviral transduction was carried out the next day. Nanog-expressing Oct4KICD45+A cells showed similar morphology to that of EGFP transfected cells (FIG. 5). Nanog over-expression, however, significantly enhanced Oct4KICD45+A cell proliferation, similar to that observed in human ES cells. Following neomycin selection for an active endogenous Oct4 promoter/regulatory region, no Nanog- or EGFP-transfected cells survived. Importantly, these results indicate that a drug-selectable population of Oct-4-expressing ES cells does not persist through the culture period necessary for differentiation. Oct-4 expression resulted in dramatic morphological changes (FIG. 5), and many of these cells survived neomycin selection. None of these cells, however, exhibited morphology typical of human ES cells. The Oct4KICD45+A cells co-expressing Nanog and Oct-4 showed morphological changes similar to those observed in cells expressing Oct-4 alone. Thus, it appears that the two key potency-determining factors, Nanog and Oct-4, alone were not sufficient to convert differentiated cells to pluripotency.

15

45

50

Cells were analyzed using cell-sorting methods before and after exposing the somatic cells to the factors. Adherent cells were individualized by trypsin treatment (0.05% Trypsin/0.5 mM EDTA, Invitrogen), and fixed in 2% paraformaldehyde for 20 minutes at room temperature. The cells 5 were filtered through a 40-um mesh, and resuspended in FACS buffer (PBS containing 2% FBS and 0.1% sodium azide). Cells grown in suspension were stained in the FACS buffer supplemented with 1 mM EDTA and 1% normal mouse serum (Sigma). Intracellular myeloperoxidase (MPO) staining was performed using Fix & Perm® reagents (Caltag Laboratories; Burlingame, Calif.). About 100 µl of cell suspension containing  $5 \times 10^5$  cells was used in each labeling. Both primary and secondary antibody incubation (where applied) were carried out at room temperature for 30 minutes. Control samples were stained with isotypematched control antibodies. After washing, the cells were resuspended in 300-500 µl of the FACS buffer, and analyzed on a FACSCalibur flow cytometer (BDIS; San Jose, Calif.) 20 using CellQuest<sup>TM</sup> acquisition and analysis software (BDIS). A total of 20,000 events were acquired. All of the antibodies used in the flow cytometry analysis are listed in Table 1. The final data and graphs were analyzed and prepared using FlowJo software (Tree Star, Inc.; Ashland, 25 Oreg.).

To further evaluate the potency-determining factors involved in reprogramming these cells, inventors explored the transduction of pools of ES cells enriched with various combinations of potency-determining factors. An exemplary pool of potency-determining factors for reprogramming 55 myeloid precursors included the fourteen potency-determining factors described in Table 2 below.

The expression of at least some of these fourteen factors in the Oct4KICD45+A cells resulted in colonies with typical morphology of pluripotent cells, such as human ES cells (FIG. 6A-left-hand photos). After neomycin selection from  $\sim 10^5$  starting Oct4KICD45+A cells, over ten colonies having the distinct ES cell morphology initially appeared. More than half of these colonies were subsequently lost to differentiation, suggesting either that over-expression of one or more introduced genes had a negative effect on the cells or that the cells continued to depend upon the foreign transgenes and gene silencing. Nevertheless, surviving colonies expressed the endogenous Oct4 promoter-driven EGFP (FIG. 7A-right-hand photos), indicating that the endogenous Oct4 promoter/regulatory region was reactivated.

In this embodiment, EGFP expression occurs when the native Oct4 promoter/regulatory region is active. In other words, undifferentiated cells are identified by a green color that disappears when the cells differentiate. Thus, the expression of endogenous Oct-4 in the primate ES cells was selectable. These colonies also expressed Oct-4, SSEA3, SSEA4, Tra-1-60 and Tra-1-81 pluripotent cell-specific markers (FIG. 6B). Similar results were obtained in reprogrammed colonies obtained using chemically defined TeSR™ medium.

Inventors randomly picked six colonies from two separate 40 transfections with the same pool of fourteen ES cell-enriched potency-determining factors, and propagated five stable colonies for at least eight weeks. Thus, inventors identified a novel approach for reprogramming primate somatic cells to become higher potency cells by administering fourteen potency-determining factors into the somatic cells.

When these cells were exposed to other combinations of potency-determining factors (i.e., Sox2, c-Myc, Oct 3/4 and Klf4) using the lentiviral delivery system described herein, reprogramming and conversion of the cells were not observed.

Inventors used the techniques described herein to screen for subsets of the fourteen tested factors that are sufficient to reprogram the tested cells. Inventors' set of fourteen sufficient factors was subsequently narrowed to a set of six, and then four genes sufficient to reprogram these cells (FIGS. 7A-B; described further below). The four genes shown to be sufficient in combination to yield stable pluripotent cell were Oct-4, Nanog, Sox2 and Lin28, as shown in FIG. 7B.

### Example 3

#### Reprogramming of Mesenchymal-like Cells with a Limited Set of Four Potency-Determining Factors after Lentiviral Transduction

To identify a more limited set of potency-determining factors capable of reprogramming differentiated cells back to pluripotency, the above-identified methods were repeated with a combination of Pou5F1 (Oct-4), Nanog, Sox2 and Lin28. Inventors used the techniques described above to screen these potency-determining factors for their ability to reprogram cells.

A different cell type was used in this example to further demonstrate the utility of the methods. The cell type was a mesenchymal-like clonal cell directly differentiated from human H1 Oct4 knock-in ES cells, as described above. As used herein, "clonal" refers to a characteristic of a population of cells derived from a common ancestor (i.e., derived from a single cell, not derived from a cell aggregate). That is, in a "clonal population," the cells display a uniform pattern of cell surface markers and morphological characteristics, as well as being substantially genetically identical.

Briefly, human H1 Oct4 knock-in ES cells (p76 to p110) were induced to differentiate in co-culture with mouse OP9 bone marrow stromal cells. See, Vodyanyk M, et al., Blood 105:617-626 (2005), incorporated herein by reference as if  $_{20}$  set forth in its entirety. Small aggregates of human H1 Oct4 knock-in ES cells were added to OP9 cells in alpha MEM supplemented with 10% FCS and 100  $\mu$ M MTG (Sigma). On the next day (day 1) of culture, the medium was changed, and the cultures were harvested on the days indicated below. 25

On day 2 of co-culture, mesodermal commitment was detected by a peak expression of transcription factors for mesendoderm (GSC, MIXL1 and T (BRACHYURY)) and early mesoderm (EVX1, LHX1 and TBX6) with Nimble-Gen® (Madison, Wis.) microarrays. During days 3-5, speci-30 fication of endoderm and mesodermal lineages was observed. This stage was accompanied with sustained expression of genes involved in epithelial-mesenchymal transition (EMT; SNAIL and SLUG) and cell expansion (HOXB2-3). It also coincided with a maximal cell prolif-35 eration rate in human H1 Oct4 knock-in ES cells/OP9 co-culture.

Differentiation of specific mesendodermal lineages was observed on days 5-7 of co-culture, when markers of developing endoderm (AFP and SERPINA1), mesenchymal 40 (SOX9, RUNX2 and PPARG2) and hematoendothelial (CDH5 and GATA1) cells were detected. However, muscleinductive factors (MYOD1, MYF5 and MYF6) were not expressed throughout seven days of co-culture. Moreover, neuroectoderm (SOX1 and NEFL) or trophectoderm (CGB 45 and PLAC) markers were not detected, indicating that OP9 cells provided an efficient inductive environment for directed hESC differentiation toward the mesendodermal pathway.

Also on day 2, a single-cell suspension of the human ES 50 cell-derived cells was harvested by successive enzymatic treatment with collagenase IV (Gibco-Invitrogen) at 1 mg/ml in DMEM/F12 medium for 15 minutes at 37° C. and 0.05% Trypsin-0.5 mM EDTA (Gibco-Invitrogen) for 10 minutes at 37° C. Cells were washed 3 times with PBS-5% 55 FBS, filtered through 70  $\mu$ M and 30  $\mu$ M cell strainers (BD Labware; Bedford, Mass.) and labeled with anti-mouse CD29-PE (AbD Serotec; Raleigh, N.C.) and anti-PE paramagnetic monoclonal antibodies (Miltenyi Biotech; Auburn, Calif.). The cell suspension was purified with magnet- 60 activated cell sorting (MACs) by passing it through a LD magnetic column attached to a Midi-MACS separation unit (Miltenyi Biotech) to obtain a negative fraction of OP9depleted, human H1 Oct4 knock-in ES cell-derived cells. Purity of human H1 Oct4 knock-in ES cell-derived cells was 65 verified using pan anti-human TRA-1-85 monoclonal antibodies (R&D Systems; Minneapolis, Minn.).

Purified human H1 Oct4 knock-in ES cell-derived cells were plated at density of 2×10<sup>4</sup> cells/ml on semisolid, serum-free medium composed of StemLine<sup>TM</sup> serum-free medium (Sigma) supplemented with 5-100 ng/ml basic fibroblast growth factor (bFGF; PeproTech; Rocky Hill, N.J.) and 1% methylcellulose (StemCell Technologies, Inc.) with or without 10-20 ng/ml PDGF-BB (PeproTech). PDGF-BB improved growth of mesenchymal cells, but was not essential for colony formation. After 14-21 days of culture, large, compact mesenchymal colonies formed, resembling embryoid bodies (EBs). Mesenchymal colonies were detected on day 7; however, 14-21 days were required to reveal actively growing colonies.

Individual mesenchymal colonies were transferred to wells of a collagen- or fibronectin-coated, 96-well plate pre-filled with 0.2 ml/well StemLine® serum-free medium supplemented with 5-100 ng/ml bFGF. After 3-4 days of culture, adherent cells from individual wells were harvested by trypsin treatment and expanded on collagen- or fibronec-tin-coated dishes in StemLine® serum-free medium with 5-100 ng/ml bFGF.

Transgene-expressing lentiviral transduction was then carried out as described above. Inventors tested the hypothesis that differentiated mesenchymal-like cells could be reprogrammed to a state of pluripotency by expressing a limited set of potency-determining factors (e.g., Oct-4, Nanog, Sox2 and Lin28). The expression of at least these four potency-determining factors resulted in colonies having cells with typical morphology of pluripotent cells, such as human ES cells (FIG. 7B; dark gray bars). As shown in FIG. 7B, the greatest number of colonies having cells with typical morphology of pluripotent cells with typical morphology of pluripotent cells with typical morphology of pluripotent cells was obtained using the full complement of Oct-4, Nanog, Sox2 or Lin28 was absent, the number of ES-like colonies was significantly attenuated (e.g., Nanog or Lin28) or absent (e.g., Oct-4 or Sox2).

In this embodiment, EGFP expression occurred when the native Oct4 promoter/regulatory region was active. In other words, undifferentiated cells were identified by a green color that was absent from differentiated cells. Thus, the expression of endogenous Oct-4 in the cells was selectable. Reprogrammed colonies also expressed Oct-4, SSEA3, SSEA4, Tra-1-60 and Tra-1-81 pluripotent cell-specific markers (data not shown).

Inventors randomly picked six colonies from two separate transfections with the same pool of fourteen ES cell-enriched potency-determining factors, and propagated five stable colonies for at least eight weeks. Thus, inventors identified a novel approach for reprogramming primate somatic cells to become higher potency cells by administering four potency-determining factors into the somatic cells.

When these cells were exposed to other combinations of potency-determining factors (i.e., Sox2, c-Myc, Oct 3/4 and Klf4) using the lentiviral delivery system described herein, reprogramming and conversion of the cells were not observed.

#### Example 4

#### Reprogramming of Mesenchymal-like Cells with a Limited Set of Two Potency-Determining Factors after Lentiviral Transduction

To identify an even more limited set of potency-determining factors capable of reprogramming differentiated cells back to pluripotency, the above-identified methods

25

65

were repeated in the mesenchymal-like cells of Example 3 with a combination of two of the following four potencydetermining factors: Oct-4, Nanog, Sox2 and Lin28. Inventors used the techniques described above to screen these potency-determining factors for their ability to reprogram 5 cells.

Transgene-expressing lentiviral transduction was then carried out as described above. Inventors tested the hypothesis that differentiated mesenchymal-like cells could be reprogrammed to a state of pluripotency by expressing fewer 10 than four potency-determining factors. The expression of at least Oct-4 and Sox2 (FIG. 7C) resulted in colonies having cells with typical morphology of pluripotent cells, such as human ES cells. Nanog and Lin28, singly and in combination, had a beneficial effect in clone recovery by improving reprogramming efficiency in human ES cell-derived mesenchymal cells to a state of pluripotency, but were essential neither for the initial appearance of reprogrammed cells nor for the expansion of reprogrammed cells.

#### Example 5

#### Reprogramming of a Differentiated Cells after Lentiviral Transduction and Expression of Four Potency-determining Factors

To further demonstrate the utility of the limited set of potency-determining factors in reprogramming differentiated cells back to pluripotency, the above-identified methods were repeated with ATCC Catalog No. CCL-186 (IMR-90; 30 ATCC), which are human fetal lung fibroblast cells (see also, Birney E, et al., Nature 447:799-816 (2007)).

Transgene-expressing lentiviral transduction was carried out as described above. That is, IMR-90 cells (0.9×106/ well), were transduced with a combination of Oct-4, Sox2, 35 out as described above. IMR-90 cells were transduced with Nanog and Lin28. Inventors tested the hypothesis that differentiated fibroblast cells could be reprogrammed to a state of pluripotency by expressing a limited set of potencydetermining factors (e.g., Oct-4, Sox2, Nanog and Lin28). Following transduction, cells were transferred to three 40 10-cm dishes seeded with irradiated mouse embryonic fibroblasts (MEFs). By day 12 post-transduction, small colonies with human ES cell morphology became visible. On day 20 post-transduction, a total of 198 colonies were visible on 3 plates. Forty-one of the colonies were picked, thirty-five of 45 which were successfully expanded for an additional three weeks. Six of these colonies were then selected for continued expansion and analysis, and the other twenty-nine were frozen.

The introduction of at least Oct-4, Sox2, Nanog and Lin28 50 resulted in colonies with typical morphology of pluripotent cells like human ES cells that had a normal karyotype. Cells from each colony likewise expressed telomerase activity and expressed human ES cell-specific surface antigens (i.e., SSEA-3, SSEA-4, Tra-1-60 and Tra1-81). For each of the 55 colonies, the expression of endogenous OCT4 and NANOG was at levels similar to that of pluripotent cells, although the exogenous expression of these genes did vary. Moreover, EB and teratoma formation demonstrated that the reprogrammed cells had a developmental potential to give rise to 60 differentiated derivatives of all three primary germ layers.

DNA fingerprint analysis confirmed that these colonies were derived from IMR-90 cells and that they were not derived from human ES cells lines (e.g., H1, H7, H9, H13 and H14).

Similar to the data obtained with differentiated mesenchymal cells, the greatest number of colonies having cells with typical morphology of pluripotent cells, such as human ES cells was obtained using the full complement of Oct-4, Nanog, Sox2 or Lin28. However, when Oct-4, Nanog, Sox2 or Lin28 were absent, the number of ES-like colonies was significantly attenuated (e.g., Nanog or Lin28) or absent (e.g., Oct-4 or Sox2).

The colonies selected for expansion and detailed characterization proliferated for at least twelve weeks and retained typical characteristics of normal pluripotent cells, even though no selection for the activation of a pluripotencyspecific gene was applied during reprogramming.

Reprogrammed cells were identified based on morphology alone (i.e., having a compact colony with high nucleus to cytoplasm ratio and prominent nucleolus). Reprogrammed cells also expressed Oct-4, SSEA3, SSEA4, Tra-1-60 and Tra-1-81 pluripotent cell-specific markers.

### Example 6

### Reprogramming of Differentiated Cells after Lentiviral Transduction and Expression of Three Potency-determining Factors

To further demonstrate the utility of the limited set of potency-determining factors in reprogramming differentiated cells back to pluripotency, the above-identified methods were repeated with the IMR-90 cells, described above. In this set of experiments, fewer potency-determining factors were used than in Example 5.

Transgene-expressing lentiviral transduction was carried a combination of three of the following: Oct-4, Sox2, Nanog and Lin28. Inventors tested the hypothesis that differentiated fibroblast cells could be reprogrammed to a state of pluripotency by expressing the even more limited set of potencydetermining factors. The expression of at least three factors resulted in colonies with typical morphology of pluripotent cells like human ES cells. Reprogrammed colonies having cells with typical morphology of pluripotent cells were obtained using the full complement of Oct-4, Sox2 and Nanog with or without Lin28. Therefore, the presence or absence of Lin28 did not affect reprogramming. However, when any of Oct-4, Nanog or Sox2 was absent, the number of reprogrammed colonies was significantly attenuated or absent.

To examine for the presence of Oct-4, Sox2, Nanog and Lin28 provirus in the reprogrammed cells, PCR with transgene-specific primer pairs (see, Table 3; one gene-specific primer and one lentiviral vector-specific primer) was carried out using genomic DNA from IMR-90 clones as template. The reactions employed the pfx DNA polymerase (Invitrogen, amplification buffer was used at 2x, and enhancer solution was used at  $3\times$ ), and the following conditions: initial denaturation for 1 minute at 95° C.; 35 cycles of 94° C. for 30 seconds, 55° C. for 30 seconds, 68° C. for 2 minutes; and followed by 68° C. for 7 minutes. PCR analysis for the transgenes showed that either all four transgenes or three transgenes (i.e., Oct-4, Sox2 and Nanog) integrated into the pluripotent cells following exposure to transgeneexpressing lentivirus vectors.

#### Example 7

#### Reprogramming of Differentiated Cells after Lentiviral Transduction and Expression of Three Potency-determining Factors

To further demonstrate the utility of the limited set of potency-determining factors in reprogramming differenti- 45 ated cells to pluripotency, the above-identified methods were repeated with ATCC Catalog No. CRL-2097 (ATCC), which are human post-natal foreskin fibroblast cells.

Transgene-expressing lentiviral transduction was carried out as described above. Post-natal fibroblast cells  $(0.6 \times 10^6)/50$ well) were transduced with a combination of Oct-4, Sox2, Nanog and Lin28. Inventors tested the hypothesis that differentiated, post-natal, fibroblast cells could be reprogrammed to a state of pluripotency by expressing a limited set of potency-determining factors and obtained promising 55 results. Following transduction, cells were transferred to three 10-cm dishes seeded with irradiated MEFs. By day 15 post-transduction, small colonies with pluripotent cell morphology became visible. On day 20 post-transduction, a total of 57 colonies were visible on the plates. Twenty-nine of the 60 colonies were picked, twenty-seven of which were successfully expanded for an additional three weeks. Four of these colonies were then selected for continued expansion and analysis, and the other twenty-three were frozen.

The expression of Oct-4, Sox2, Nanog and Lin28 resulted 65 in colonies having cells with typical morphology of pluripotent cells, such as human ES cells, and a normal karyo-

type. Reprogrammed colonies likewise expressed telomerase activity and expressed pluripotent cell-specific markers (i.e., SSEA-3, SSEA-4, Tra-1-60 and Tra1-81). For each, endogenous OCT4 and NANOG was expressed at levels similar to that observed in human pluripotent cells. although the exogenous expression of these genes varied. Moreover, EB and teratoma formation demonstrated that the reprogrammed cells had a developmental potential to give rise to differentiated derivatives of all three primary germ layers. However, in contrast to the iPS cells obtained from IMR-90 cells, iPS cells derived from CRL-2097 cells showed a variation in the lineages apparent in teratomas examined at five weeks. Two of the iPS cell colonies showed neural differentiation; whereas the other two colonies showed multiple foci of columnar epithelial cells, reminiscent of primitive ectoderm.

DNA fingerprint analysis confirmed that these colonies were derived from the original cell line and confirmed that 20 they were not derived from human ES cells lines (e.g., H1, H7, H9, H13 and H14).

Similar to the data obtained after transduction of differentiated mesenchymal cells, the greatest number of colonies having cells with typical morphology of human pluripotent cells were obtained using the full complement of Oct-4, Sox2, Nanog and Lin28. Interestingly, one cell line lacked Lin28, confirming that Lin28 was not essential for reprogramming somatic cells.

The colonies selected for expansion and detailed characterization proliferated for at least twelve weeks and retained typical characteristics of normal human pluripotent cells, even though no selection for the activation of a pluripotency-specific gene was applied during reprogramming.

Reprogrammed cells were identified based on morpholgrammed cells also expressed Oct-4, SSEA3, SSEA4, Tra- 35 ogy alone (i.e., having a compact colony with high nucleus to cytoplasm ratio and prominent nucleolus). Reprogrammed cells also expressed Oct-4, SSEA3, SSEA4, Tra-1-60 and Tra-1-81 pluripotent cell-specific markers.

When these cells were exposed to other combinations of 40 factors (i.e., Sox2, c-Myc, Oct 3/4 and Klf4) using the lentiviral delivery system described herein, reprogramming and conversion of the cells were not observed.

#### Example 8

#### Reprogramming of Differentiated Cells after Lentiviral Transduction and Expression of Four Potency-determining Factors

To further demonstrate the utility of the limited set of potency-determining factors in reprogramming differentiated cells to pluripotency, the above-identified methods were repeated with ATCC Catalog No. CRL-2106 (SK46; ATCC), which are human adult skin cells.

Transgene-expressing lentiviral transduction was carried out as described above. That is, skin cells  $(2.0 \times 10^5/\text{well})$ were transduced with a combination of Oct-4, Sox2, Nanog and Lin28. Inventors tested the hypothesis that adult skin cells could be reprogrammed to a state of pluripotency by expressing a limited set of potency-determining factors and obtained promising results. Following transduction, cells were transferred to three 10-cm dishes seeded with irradiated mouse embryonic fibroblasts (MEFs). After 10 days in human ES cell culture medium human ES cell culture medium conditioned with irradiated MEFs was used to support cell growth. By day 18 post-transduction, small colonies with pluripotent cell morphology became visible.

The expression of Oct-4, Sox2, Nanog and Lin28 resulted in colonies having cells with typical morphology of pluripotent cells (see, FIG. **8**A), such as human ES cells (i.e., having a compact colony with high nucleus to cytoplasm ratio and prominent nucleolus). As shown in FIG. **8**B, the 5 reprogrammed cells also expressed cell surface markers typical of pluripotent cells; SK46 cells (control), however, did not. However, the reprogrammed colonies from adult skin cells appeared later than the cells in Example 7 and had a lower reprogramming efficiency than the cells in Example 10 7.

#### Example 9

Increasing Reprogramming Efficiency by Linking Potency-determining Factors on a Single Construct

To increase the reprogramming efficiency, the aboveidentified methods were repeated using the construct shown in FIG. **4**A; however, either Oct-4 or Sox2 were inserted in <sub>20</sub> the transgene section, and Sox2 optionally replaced the puromycin resistance gene. The constructs were then expressed either in 293FT cells or in OCT4 knock-in human H1 ES cells (p6).

Transgene-expressing lentiviral transduction was carried  $_{25}$  out as described above. That is, 293FT cells or mesenchymal cells ( $\sim 2 \times 10^5$  cells/well of 6-well plate, seeded overnight) were transduced with various transgene combinations. Cells were transferred to 10 cm MEF dish (1 well of 6-well plate to 1×10 cm MEF dish) following the overnight incubation  $_{30}$  with lentivirus. Geneticin selection (50 µg/ml) for an active, endogenous, OCT4 promoter was carried out between day 11 to 15 post transduction. iPS colonies were counted on day 16.

FIG. **9**A demonstrates that Oct-4 and Sox2 expression occurred in 293FT cells following transfection (see, e.g.,

SEQUENCE LISTING

lanes 1-3). In FIGS. **9**A-B, pSin4-EF2-Oct4-IRES1-Sox2 is abbreviated as OS-IRES1; pSin4-EF2-Oct4-IRES2-Sox2 is abbreviated as OS-IRES2; pSin4-EF2-Oct4-F2A-Sox2 is abbreviated as OS-F2A; pSin4-EF2-Oct4-IRES1-puro is abbreviated as O; and pSin4-EF2-Sox2-IRES1-puro is abbreviated as S.

FIG. **9**B shows that reprogramming efficiency increased in mesenchymal cells derived from OCT4 knock-in human H1 ES cells (p6) when Oct-4 and Sox2 were provided on the same construct (IRES1 is a very low-efficiency internal ribosome entry site; whereas IRES2 is a high-efficiency internal ribosome entry site). OS-IRES2+N+L (the highefficiency IRES) showed an approximate four fold increase in reprogramming efficiency when compared to O+S, O+S+ N+L or OS-IRES1 (the low-efficiency IRES)+N+L. Therefore, providing the potency-determining factors in one construct that provides for approximately equal expression levels of each can improve reprogramming efficiency.

It is understood that certain adaptations of the invention described in this disclosure are a matter of routine optimization for those skilled in the art, and can be implemented without departing from the spirit of the invention, or the scope of the appended claims.

All publications and patents mentioned in the above specification are herein incorporated by reference. Various modifications and variations of the described method and system of the invention will be apparent to those skilled in the art without departing from the scope and spirit of the invention. It is understood, however, that examples and embodiments of the present invention set forth above are illustrative and not intended to confine the invention. The invention embraces all modified forms of the examples and embodiments as come within the scope of the following claims.

We claim:

**1**. A method of reprogramming human somatic cells, the method comprising the steps of:

- introducing a non-integrating vector encoding Oct-4 and Sox2 and at least one of Nanog and Lin28 operably linked to one or more heterologous promoters into isolated human somatic cells; and
- culturing the somatic cells under embryonic stem (ES) cell culture conditions such that pluripotent reprogrammed cells are obtained.

2. The method of claim 1, wherein the somatic cells are obtained from a post-natal individual.

**3**. The method of claim **1**, wherein the somatic cells are obtained by in vitro differentiation of a stem cell.

4. The method of claim 1, wherein the non-integrating vector is an Epstein-Barr virus nuclear antigen (EBNA)-based vector.

**5**. The method of claim **1**, wherein the reprogrammed cells (i) express a cell marker selected from the group consisting of Oct-4, SSEA3, SSEA4, Tra-1-60 and Tra-1-81; (ii) exhibit morphology characteristic of pluripotent cells; and (iii) form teratomas when introduced into an immuno-compromised animal.

**6**. A method of reprogramming human somatic cells, the method comprising the steps of:

38

- introducing a non-integrating vector encoding Oct-4, Sox2, and at least one of Nanog and Lin28 operably linked to one or more heterologous promoters into isolated human somatic cells; and
- culturing the somatic cells under embryonic stem cell 5 culture conditions such that reprogrammed cells having a higher potency level than the somatic cells are obtained.

7. A method of producing an induced pluripotent stem (iPS) cell, comprising the steps of:

- introducing one or a plurality of non-integrating vectors into a human somatic cell in vitro, wherein the one or plurality of non-integrating vectors comprise nucleic acid sequences encoding potency-determining factors Oct 4, Sox 2, and at least one of Nanog and Lin28; and culturing the somatic cell in a medium that supports
- pluripotent stem cells such that iPS cells are obtained. 8. The method of claim 7, wherein the one or plurality of

non-integrating vectors comprises an IRES coding region. 9. The method of claim 7, wherein a plurality of non- 20

integrating vectors are introduced into a single somatic cell.

10. The method of claim 6, wherein the reprogrammed cells are free of any vector component used to introduce the reprogramming factors.

**11**. The method of claim **7**, wherein the culturing step is performed without selection.

**12**. The method of claim 7, wherein the iPS cells do not comprise the one or the plurality of non-integrating vectors.

**13**. A method of producing an induced pluripotent stem cell, comprising the steps of:

introducing one or more Epstein-Barr virus nuclear antigen (EBNA)-based non-integrating vectors encoding Oct 4, Sox 2, and at least one of Nanog and Lin28 operably linked to one or more heterologous promoters into a human somatic cell in vitro; and

culturing the somatic cell in a medium that supports pluripotent stem cells such that iPS cells are obtained.

14. The method of claim 13, wherein two or more EBNA-based non-integrating vectors comprising different genes from each other are introduced into the somatic cell.

**15**. The method of claim **14**, wherein the two or more EBNA-based non-integrating vectors comprising different genes from each other are introduced into the somatic cell concurrently.

16. The method of claim 1, wherein the plurality of factors are introduced into the somatic cells on one or more EBNA-based non-integrating vectors.

17. The method of claim 6, wherein the plurality of factors are introduced into the somatic cells on one or more EBNA-based non-integrating vectors.
