(57) **ABSTRACT**

An inverter includes a plurality of inverter legs that each includes first, second, and third switches. A first control line connected to the first switch receives a first control signal. A second control line connected to the second switch receives a second control signal. A third control line connected to the third switch receives the first control signal. The first, second, and third switches are connected sequentially in series. A first connector line is connected between the first switch and the second switch and to a first winding of an electric machine. A second connector line is connected between the second switch and the third switch and to a second winding of the electric machine. The second control signal is complementary to the first control signal.

INVERTER FOR COMMON MODE VOLTAGE CANCELLATION

BACKGROUND

In electrical systems, there is typically a power source that produces power, and an electrical load that consumes the produced power. The various sources and loads often have different electrical properties and require power electronics to transfer power between components. A power converter is an electrical device for converting electrical energy from one form to another, such as between alternating current (AC) and direct current (DC), between different voltages or frequencies, or a combination of these. A specific type of converter, called an inverter, changes DC to AC. In a drive system, a voltage source inverter (VSI) may be used to transfer real power from a DC power source to an AC load.

In a three-phase AC system, the common-mode (CM) voltage can be defined as a voltage difference between the power source ground and the neutral point of a three-phase load. If the load is an AC motor, the neutral point of the load means the stator neutral of the motor. Inverters generate CM voltages relative to the power source ground that cause coupling currents through parasitic capacitances inside the motor (load). The main source of bearing currents is the capacitance-coupling currents that return via the motor bearings back to the ground. The bearing damage in inverter-driven motors is mainly caused by the shaft voltage and the bearing currents created by the common-mode voltage.

Conventional VSIs consist of two or three phase-legs, each of which is a series connection of two semiconductor switches. During normal operation, the output potential of each phase leg with respect to ground is continuously switched between a positive and a negative DC bus potential based on a pulse width modulation of the switches. As a result, the CM voltage imposed on the load also exhibits six step-changes during each switching cycle. Each step-change induces a charging or discharging current into the parasitic capacitances between load and ground that leads to issues such as electromagnetic interference emissions, inverter losses, and motor damage. CM chokes and filters may be used to mitigate the CM voltage induced issues. However, since CM chokes have to block a significant amount of CM voltage, they are bulky in size, and constitute a large portion of the product cost.

SUMMARY

In an example embodiment, an inverter is provided. The inverter includes, but is not limited to, a positive direct current (DC) line, a negative DC line, and a plurality of inverter legs. Each inverter leg includes, but is not limited to, a first switch, a second switch, a third switch, a first switch control line, a second switch control line, and a third switch control line. The first switch control line is connected to the first switch and configured to receive a first control signal to control an on or off state of the first switch. The second switch control line is connected to the second switch and configured to receive a second control signal to control an on or off state of the second switch. The third switch control line is connected to the third switch and configured to receive the first control signal to control an on or off state of the third switch. A first connector line is connected between the first switch and the second switch. A second connector line is connected between the second switch and the third switch. The first switch, the second switch, and the third switch are connected sequentially in series between the

2

positive DC line and the negative DC line. The first connector line is configured to be connected to a first winding of an electric machine. The second connector line is configured to be connected to a second winding of the electric machine. The second control signal is complementary to the first control signal.

In another example embodiment, an electric machine drive is provided. The electric machine drive includes, but is not limited to, the inverter and a controller. The controller includes, but is not limited to, a first control signal line and a second control signal line. The controller is configured to generate a first control signal on the first control signal line and to generate a second control signal on the second control signal line. The first control signal is complementary to the second control signal. The first control signal controls an on or off state of the first switch and the third switch together. The second control signal controls an on or off state of the second switch.

In yet another example embodiment, an electric machine system is provided. The electric machine drive includes, but is not limited to, the inverter, the controller, and an electric machine. The electric machine includes, but is not limited to, a stator, a rotor configured to rotate relative to the stator, a first winding wound around at least a first portion of the stator, and a second winding wound around at least a second portion of the stator. The first connector line is configured to be connected to the first winding. The second connector line is configured to be connected to the second winding.

Other principal features of the disclosed subject matter will become apparent to those skilled in the art upon review of the following drawings, the detailed description, and the appended claims.

BRIEF DESCRIPTION OF THE DRAWINGS

Illustrative embodiments of the disclosed subject matter will hereafter be described referring to the accompanying drawings, wherein like numerals denote like elements.

FIG. 1 is a block diagram of an electric machine system connected to an input source in accordance with an illustrative embodiment.

FIG. 2 depicts an electric machine of FIG. 1 in accordance with an illustrative embodiment.

FIG. 3 depicts a switch circuit in accordance with an illustrative embodiment.

FIG. 4 is a block diagram of a 3-phase inverter of the electric machine system of FIG. 1 in accordance with an illustrative embodiment.

FIG. 5 is a circuit diagram of an inverter of the electric machine system of FIG. 1 in accordance with a first illustrative embodiment.

FIG. 6 is a circuit diagram of an inverter of the electric machine system of FIG. 1 in accordance with a second illustrative embodiment.

FIG. 7 shows a CM voltage generated using the inverter of FIG. 6.

FIG. 8 shows a ground leakage current comparison between a conventional inverter and the inverter of FIG. 6.

FIG. 9 is a circuit diagram of an inverter of the electric machine system of FIG. 1 in accordance with a third illustrative embodiment.

FIG. 10 is a circuit diagram of an inverter of the electric machine system of FIG. 1 in accordance with a fourth illustrative embodiment.

FIGS. 11A and 11B depict a winding configuration of the electric machine of FIG. 1 in accordance with a first illustrative embodiment.

FIGS. 12A and 12B depict a winding configuration of the electric machine of FIG. 1 in accordance with a second illustrative embodiment.

FIG. 13 depicts a general winding configuration of a dual-voltage, 9-lead electric machine in accordance with an illustrative embodiment.

FIG. 14 depicts a winding configuration of the electric machine of FIG. 1 created by disconnecting and reconnecting the general winding configuration of FIG. 13.

DETAILED DESCRIPTION

Referring to FIG. 1, an electric machine system 100 may include a controller 104, an inverter 106, and an electric machine 108. Electric machine 108 may be a motor such as an induction motor, a reluctance motor, a synchronous motor, etc. that may include windings and/or permanent magnets to generate mechanical power. Inverter 106 converts DC power from DC input source 102 to the AC power supplied to electric machine 108 to generate the mechanical power.

A direct current (DC) input source 102 is electrically connected to controller 104 and to inverter 106. DC input source 102 can include one or more DC sources. DC input source 102 may be a DC grid, batteries, a dc output of a single-phase or multi-phase passive or active rectifier, etc. that provides approximately constant instantaneous power flow. DC input source 102 may provide DC power and DC input source measured signals to controller 104. DC input source 102 provides DC power to inverter 106. Inverter 106 provides alternating current (AC) power to electric machine 108.

Controller 104 may be electrically connected to DC input source 102, inverter 106, and electric machine 108. Controller 104 controls the supply of power by inverter 106 to electric machine 108 through control signals input to inverter 106. The control signals may be generated by controller 104 based on the DC input source measured signals received from DC input source 102 and signals measured and received from electric machine 108. In an illustrative embodiment, controller 104 implements a closed loop current control to determine the control signals though other control algorithms may be implemented by controller 104. Illustrative control methods include direct/indirect field orientation control and direct torque control. Illustrative modulation techniques include sine pulse width modulation (PWM), space vector PWM, discrete PWM, and random PWM. Illustrative sensing techniques include a hall effect sensor, an encoder, a resolver, and self-sensing.

Referring to FIG. 2, an AC motor 200 is shown in accordance with an illustrative embodiment. AC motor 200 is merely an example of electric machine 108. AC motor 200 may include a rotor 202 and a stator 204 with a stator winding 206 in various arrangements as understood by a person of skill in the art. AC motor 200 may be an AC electric motor in which the electric current in a rotor winding needed to produce torque is induced by electromagnetic induction from a magnetic field formed by a current in stator winding 206. For illustration, rotor 202 of AC motor 200 may be wound type, squirrel-cage type, etc. AC motor 200 further may be configured to have any size rating. A shaft 208 is mounted to rotate with rotor 202.

Stator winding 206 may include one or more sets of windings that carry current having one or more phases of electrical energy that are distributed around stator 206. Rotor 202 is mounted relative to stator 204 in various axial and radial arrangements. The illustrative embodiment of FIG. 2,

shows an interior, radial mounted rotor 202 that is mounted within stator 204. Stator 204 is mounted within a motor housing 210. Controller 104 and inverter 106 can be mounted inside a controller housing 212 of electric machine 108 and connected to stator winding 206 as well as other components of AC motor 200.

Referring to FIG. 3, a switch 300 is shown in accordance with an illustrative embodiment. Switch 300 may include a transistor 302 and a diode 304. Transistor 302 may include a drain (or collector) 306, a gate (or base) 308, and a source (or emitter) 310 as in a metal-oxide-semiconductor field-effect transistor (MOSFET), an insulated-gate bipolar transistor (IGBT), a bipolar junction transistor, etc. Diode 304 is connected anti-parallel across source 310 and drain 306 of transistor 302. Depending on the switching logic and whether transistor 302 is an n-type or a p-type, drain 306 and source 310 may be reversed. A voltage applied to gate 308 determines a switching state of transistor 302. In an illustrative embodiment, transistor 302 is an insulated-gate field-effect transistor such as a MOSFET, IGBT, Gallium Nitride (GaN) device, Silicon Carbide (SiC) device, other Silicon based device, etc.

A switch control line 312 is electrically connected between gate 308 and controller 104 to provide a control signal to switch 300. Depending on an amplitude of the control signal, switch 300 allows current flow from drain 306 to source 310 and onto a source line 316, or blocks current flow from drain 306 to source 310 to allow a current flow through diode 304 from source line 316 to a drain line 314 that bypasses transistor 302. Current flow through transistor 302 from drain 306 to source 310 may be termed an "on" state of switch 300. Blocking current flow through transistor 302 from drain 306 to source 310 may be termed an "off" state of switch 300. When switch 300 is in the "off" state, current can flow through diode 304 of switch 300.

Referring to FIG. 4, a block diagram of inverter 106 is shown in accordance with an illustrative embodiment. A V_{dc} 400 is applied across a positive DC line 402 and a negative DC line 403. An input current 404 is provided through positive DC line 402, and an output current 406 is provided through negative DC line 403. V_{dc} 400 represents the voltage from DC input source 102. In the illustrative embodiment, inverter 106 includes two sets of three phase lines that output a current. A first-phase current I_a through a first-phase line 408a, a second-phase current I_b through a second-phase line 410a, a third-phase current I_c through a third-phase line 412a, a fourth-phase current I_a' through a fourth-phase line 408b, a fifth-phase current I_b' through a fifth-phase line 410b, and a sixth-phase current I_c' through a third sixth phase line 412b. The phase currents provide AC power to electric machine 108. In the illustrative embodiment, inverter 106 is a three-phase inverter though a different number of phases may be output from inverter 106 in alternative embodiments.

Referring to FIG. 5, a circuit diagram of a first inverter 106a is shown in accordance with an illustrative embodiment. First inverter 106a is a first illustrative embodiment of inverter 106. A capacitor 500 may be connected across V_{dc} 400 between positive DC line 402 and negative DC line 403 of first inverter 106a. First inverter 106a may include a first leg 502a and a second leg 502b. First leg 502a includes a first switch 504a, a second switch 506a, and a third switch 508a connected sequentially in series between positive DC line 402 and negative DC line 403. Similarly, second leg 502b includes a first switch 504b, a second switch 506b, and a third switch 508b connected sequentially in series between positive DC line 402 and negative DC line 403.

Each of first switch **504a**, second switch **506a**, and third switch **508a** of first leg **502a** and of first switch **504b**, second switch **506b**, and third switch **508b** of second leg **502b** is an instance of switch **300** with transistor **302** and diode **304**. As a result, transistor **302** of each switch of each leg of first inverter **106a** includes drain **306**, gate **308**, and source **310**.

Drain **306** of first switch **504a** of first leg **502a** is connected to positive DC line **402**. Source **310** of first switch **504a** of first leg **502a** is connected to drain **306** of second switch **506a** of first leg **502a**. Source **310** of second switch **506a** of first leg **502a** is connected to drain **306** of third switch **508a** of first leg **502a**. Source **310** of third switch **508a** of first leg **502a** is connected to negative DC line **403**.

Drain **306** of first switch **504b** of second leg **502b** is connected to positive DC line **402**. Source **310** of first switch **504b** of second leg **502b** is connected to drain **306** of second switch **506b** of second leg **502b**. Source **310** of second switch **506b** of second leg **502b** is connected to drain **306** of third switch **508b** of second leg **502b**. Source **310** of third switch **508b** of second leg **502b** is connected to negative DC line **403**.

A first connector line **510a** of first leg **502a** is connected between source **310** of first switch **504a** of first leg **502a** and drain **306** of second switch **506a** of first leg **502a**. A second connector line **512a** of first leg **502a** is connected between source **310** of second switch **506a** of first leg **502a** and drain **306** of third switch **508a** of first leg **502a**.

A first connector line **510b** of second leg **502b** is connected between source **310** of first switch **504b** of second leg **502b** and drain **306** of second switch **506b** of second leg **502b**. A second connector line **512b** of second leg **502b** is connected between source **310** of second switch **506b** of second leg **502b** and drain **306** of third switch **508b** of second leg **502b**.

A first stator winding **514a** is connected between first connector line **510a** of first leg **502a** and first connector line **510b** of second leg **502b**. A second stator winding **514b** is connected between second connector line **512a** of first leg **502a** and second connector line **512b** of second leg **502b**. For illustration, first stator winding **514a** and second stator winding **514b** are wound about stator **206** of AC motor **200**.

Though not shown, each gate **308** of first switch **504a**, second switch **506a**, and third switch **508a** of first leg **502a** and of first switch **504b**, second switch **506b**, and third switch **508b** of second leg **502b** is connected to controller **104** to receive control signals to control a switching state of each switch. A first control signal is provided simultaneously to first switch **504a** and to third switch **508a** of first leg **502a**. A second control signal is inverted relative to or “complementary to” the first control signal and is applied simultaneously to second switch **506a** of first leg **502a**. Thus, if the first control signal is “A” to switch on first switch **504a** and third switch **508a** of first leg **502a**, the second control signal is “-A” to switch off second switch **506b** of first leg **502a**, and vice versa.

A third control signal is provided simultaneously to first switch **504b** and to third switch **508b** of second leg **502b**. A fourth control signal is inverted relative to or “complementary to” the third control signal and is applied simultaneously to second switch **506b** of second leg **502b**. As understood by a person of skill in the art, the first control signal, the second control signal, the third control signal, and the fourth control signal are pulse width modulated signals selected to generate an AC waveform from the DC input waveform by rapidly switching the states of the switches of first inverter **106a** on and off.

A first voltage results across first stator winding **514a**, and a first current flows through first stator winding **514a**. Correspondingly, a second voltage and a second current result across and flow through second stator winding **514b**. The second voltage and the second current are 180 degrees out of phase relative to the first voltage and the first current, respectively.

First inverter **106a** cancels a total CM voltage by generating two equal-amplitude, opposite-signed CM voltages on first stator winding **514a** and second stator winding **514b**. As a result, AC motor **200**, which is an illustrative embodiment of electric machine **108**, remains at ground potential, and no current flows to ground.

Second switch **506a** of first leg **502a** and second switch **506b** of second leg **502b** may be rated to support a maximum DC power (voltage). First switch **504a** and third switch **508a** of first leg **502a** and first switch **504b** and third switch **508b** of second leg **502b** may be rated to support half the maximum DC power because the power (voltage) is split between the first and third switches of each leg.

Referring to FIG. 6, a circuit diagram of a second inverter **106b** is shown in accordance with an illustrative embodiment. Second inverter **106a** is a second illustrative embodiment of inverter **106**. Capacitor **500** may be connected across V_{dc} **400** between positive DC line **402** and negative DC line **403** of second inverter **106b**. Negative DC line **403** may be grounded at a ground potential.

Second inverter **106b** may include first leg **502a**, second leg **502b**, and a third leg **502c**. Similar to first leg **502a** and second leg **502b**, third leg **502c** includes a first switch **504c**, a second switch **506c**, and a third switch **508c** connected sequentially in series between positive DC line **402** and negative DC line **403**. Each of first switch **504c**, second switch **506c**, and third switch **508c** of third leg **502c** is an instance of switch **300** with transistor **302** and diode **304**. As a result, transistor **302** of each switch of each leg of second inverter **106b** includes drain **306**, gate **308**, and source **310**.

Drain **306** of first switch **504c** of third leg **502c** is connected to positive DC line **402**. Source **310** of first switch **504c** of third leg **502c** is connected to drain **306** of second switch **506c** of third leg **502c**. Source **310** of second switch **506c** of third leg **502c** is connected to drain **306** of third switch **508c** of third leg **502c**. Source **310** of third switch **508c** of third leg **502c** is connected to negative DC line **403**.

A first connector line **510c** of third leg **502c** is connected between source **310** of first switch **504c** of third leg **502c** and drain **306** of second switch **506c** of third leg **502c**. A second connector line **512c** of third leg **502c** is connected between source **310** of second switch **506c** of third leg **502c** and drain **306** of third switch **508c** of third leg **502c**.

A first stator winding **600a** is connected between first connector line **510a** of first leg **502a** and a first common neutral connector **606a**. A second stator winding **602a** is connected between first connector line **510b** of second leg **502b** and first common neutral connector **606a**. A third stator winding **604a** is connected between first connector line **510c** of third leg **502c** and first common neutral connector **606a**. For illustration, first stator winding **600a**, second stator winding **602a**, and third stator winding **604a** are wound about stator **206** of AC motor **200** and connected to form a first three-phase wye connection configuration. In an alternative embodiment, first stator winding **600a**, second stator winding **602a**, and third stator winding **604a** may be wound about stator **206** of AC motor **200** and connected to form a first three-phase delta connection configuration.

First stator winding **600a** is supplied a first current I_a through first connector line **510a** of first leg **502a**. Second

stator winding **602a** is supplied a second current I_b through first connector line **510b** of second leg **502b**. Third stator winding **604a** is supplied a third current I_c through first connector line **510c** of third leg **502c**. As understood by a person of skill in the art, the currents applied to the machine windings are $360/n$ degrees out of phase with respect to each other, where n represents a number of phases. Thus, I_a , I_b , and I_c are 120 degrees out of phase with respect to each other.

A fourth stator winding **600b** is connected between second connector line **512a** of first leg **502a** and a second common neutral connector **606b**. A fifth stator winding **602b** is connected between second connector line **512b** of second leg **502b** and second common neutral connector **606b**. A sixth stator winding **604b** is connected between second connector line **512c** of third leg **502c** and second common neutral connector **606b**. For illustration, fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b** are wound about stator **206** of AC motor **200** and connected to form a second three-phase wye connection configuration. In an alternative embodiment, fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b** may be wound about stator **206** of AC motor **200** and connected to form a second three-phase delta connection configuration.

Fourth stator winding **600b** is supplied a fourth current I_a' through second connector line **512a** of first leg **502a**. Fifth stator winding **602b** is supplied a second current I_b' through second connector line **512b** of second leg **502b**. Sixth stator winding **604b** is supplied a third current I_c' through second connector line **512c** of third leg **502c**. As understood by a person of skill in the art, the currents applied to the windings of electric machine **108** are $360/n$ degrees out of phase with each other. Thus, I_a' , I_b' , and I_c' are 120 degrees out of phase with respect to each other. I_a and I_a' are 180 degrees out of phase with respect to each other. I_b and I_b' are 180 degrees out of phase with respect to each other. I_c and I_c' are 180 degrees out of phase with respect to each other.

Gate **308** of first switch **504a** and third switch **508a** of first leg **502a** are both connected to a first control line **608a** of controller **104** to receive a first control signal to control the switching state of each switch together. Gate **308** of second switch **506b** of first leg **502a** is connected to a second control line **610a** of controller **104** to receive a second control signal to control the switching state of second switch **506b** of first leg **502a**. The second control signal is inverted relative to or “complementary to” the first control signal and is applied simultaneously to second switch **506a** of first leg **502a**.

Gate **308** of first switch **504b** and third switch **508b** of second leg **502b** are both connected to a third control line **608b** of controller **104** to receive a third control signal to control the switching state of each switch together. Gate **308** of second switch **506b** of second leg **502b** is connected to a fourth control line **610b** of controller **104** to receive a fourth control signal to control the switching state of second switch **506b** of second leg **502b**. The fourth control signal is inverted relative to or “complementary to” the third control signal and is applied simultaneously to second switch **506b** of second leg **502b**.

Gate **308** of first switch **504c** and third switch **508c** of third leg **502c** are both connected to a fifth control line **608c** of controller **104** to receive a fifth control signal to control the switching state of each switch together. Gate **308** of second switch **506c** of third leg **502c** is connected to a sixth control line **610c** of controller **104** to receive a sixth control signal to control the switching state of second switch **506c** of third leg **502c**. The sixth control signal is inverted relative

to or “complementary to” the fifth control signal and is applied simultaneously to second switch **506c** of third leg **502c**.

As understood by a person of skill in the art, the first control signal, the second control signal, the third control signal, the fourth control signal, the fifth control signal, and the sixth control signal are pulse width modulated signals selected to generate an AC waveform from the DC input waveform by rapidly switching the states of the switches of second inverter **106b** on and off. For illustration, there may be eight possible switching vectors for second inverter **106b**, **V0** through **V7** with six active switching vectors and two zero vectors based on the complementary operation of the second switch of each leg relative to the first and third switches of each leg, and the common control of the first and third switches of each leg. As a result, control algorithms for inverters that include two switches per leg may be used to control operation of second inverter **106b** subject to the common control of the first and third switches of each leg.

Second switch **506a** of first leg **502a**, second switch **506b** of second leg **502b**, and second switch **506c** of third leg **502c** may be rated to support a maximum DC power (voltage). First switch **504a** and third switch **508a** of first leg **502a**, first switch **504b** and third switch **508b** of second leg **502b**, and first switch **504c** and third switch **508c** of third leg **502c** may be rated to support half the maximum DC power because the power (voltage) is split between the first and third switches of each leg.

Second inverter **106b** cancels a total CM voltage by generating two equal-amplitude, opposite-signed CM voltages on the two sets of three phase windings, a first set of windings that includes first stator winding **600a**, second stator winding **602a**, and third stator winding **604a**, and a second set of windings that includes fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b**. As a result, AC motor **200**, which is an illustrative embodiment of electric machine **108**, remains at ground potential, and no current flows to ground.

Referring to FIG. 7, a CM voltage generated using second inverter **106** is shown. A first CM voltage curve **700** shows the CM voltage generated on the first set of windings. A second CM voltage curve **702** shows the CM voltage generated on the second set of windings. A third CM voltage curve **704** shows the total CM voltage generated, which is zero as expected due to the cancellation effect.

Referring to FIG. 8, a ground leakage current comparison is shown between second inverter **106** and a conventional inverter that includes two switches per leg. A first leakage current curve **800** shows the zero ground leakage current that results using second inverter **106**. A second leakage current curve **802** shows the ground leakage current spikes that result using the conventional inverter when the controller switches the state of the switches of the conventional inverter. Cancellation of the total CM voltage eliminates the ground leakage current in electric machine **108** using second inverter **106**.

Referring to FIG. 9, a circuit diagram of a third inverter **106c** is shown in accordance with an illustrative embodiment. Third inverter **106c** is a third illustrative embodiment of inverter **106**. Capacitor **500** may be connected across V_{dc} **400** between positive DC line **402** and negative DC line **403** of third inverter **106c**, which may be grounded.

Third inverter **106c** may include first leg **502a**, second leg **502b**, third leg **502c**, . . . , and an n th leg **502n**. Similar to first leg **502a**, second leg **502b**, and third leg **502c**, n th leg **502n** includes a first switch **504n**, a second switch **506n**, and

a third switch **508n** connected sequentially in series between positive DC line **402** and negative DC line **403**.

Each of first switch **504n**, second switch **506n**, and third switch **508n** of nth leg **502n** is an instance of switch **300** with transistor **302** and diode **304**. As a result, transistor **302** of each switch of each leg of third inverter **106c** includes drain **306**, gate **308**, and source **310**.

Drain **306** of first switch **504n** of nth leg **502n** is connected to positive DC line **402**. Source **310** of first switch **504n** of nth leg **502n** is connected to drain **306** of second switch **506n** of nth leg **502n**. Source **310** of second switch **506n** of nth leg **502n** is connected to drain **306** of third switch **508n** of nth leg **502n**. Source **310** of third switch **508n** of nth leg **502n** is connected to negative DC line **403**.

A first connector line **510n** of nth leg **502n** is connected between source **310** of first switch **504n** of nth leg **502n** and drain **306** of second switch **506n** of nth leg **502n**. A second connector line **512n** of nth leg **502n** is connected between source **310** of second switch **506n** of nth leg **502n** and drain **306** of third switch **508n** of nth leg **502n**.

A first nth stator winding **608a** is connected between first connector line **510n** of nth leg **502n** and first common neutral connector **606a**. A second nth stator winding **608b** is connected between second connector line **512n** of nth leg **502n** and second common neutral connector **606b**. For illustration, first nth stator winding **608a** and second nth stator winding **608b** are also wound about stator **206** of AC motor **200**. First stator winding **600a**, second stator winding **602a**, third stator winding **604a**, and first nth stator winding **608a** are connected to form a first n-phase wye connection configuration. First stator winding **600b**, second stator winding **602b**, third stator winding **604b**, and second nth stator winding **608b** are connected to form a second n-phase wye connection configuration. In an alternative embodiment, first stator winding **600a**, second stator winding **602a**, third stator winding **604a**, and second nth stator winding **608a** may be connected to form a first n-phase polygon connection configuration, and first stator winding **600b**, second stator winding **602b**, third stator winding **604b**, and second nth stator winding **608b** may be connected to form a second n-phase polygon connection configuration.

First nth stator winding **608a** is supplied a first nth current I_n through first connector line **510n** of nth leg **502n**. Second nth stator winding **608a** is supplied a second nth current I_n' through second connector line **512n** of nth leg **502n**. I_n and I_n' are 180 degrees out of phase with respect to each other.

Gate **308** of first switch **504n** and third switch **508n** of nth leg **502n** are both connected to a first nth control line **608n** of controller **104** to receive a first nth control signal to control the switching state of each switch together. Gate **308** of second switch **506n** of nth leg **502n** is connected to a second nth control line **610n** of controller **104** to receive a second nth control signal to control the switching state of second switch **506b** of nth leg **502n**. The second nth control signal is inverted relative to or "complementary to" the first nth control signal and is applied simultaneously to second switch **506n** of nth leg **502n**. The first nth control signal and the second nth control signal are also pulse width modulated signals selected to generate an AC waveform from the DC input waveform by rapidly switching the states of the switches of third inverter **106c** on and off. The AC waveform includes $n \times 2$ phases.

Second switch **506n** of nth leg **502n** may be rated to support a maximum DC power (voltage). First switch **504n** and third switch **508n** of nth leg **502n** may be rated to

support half the maximum DC power because the power (voltage) is split between the first and third switches of each leg.

Third inverter **106c** cancels a total CM voltage by generating two equal-amplitude, opposite-signed CM voltages on the two sets of n-phase windings, set one that includes first stator winding **600a**, second stator winding **602a**, third stator winding **604a**, . . . , and first nth stator winding **608a**, and set two that includes fourth stator winding **600b**, fifth stator winding **602b**, sixth stator winding **604b**, . . . , and second nth stator winding **608b**. As a result, AC motor **200**, which is an illustrative embodiment of electric machine **108**, remains at ground potential, and no current flows to ground.

Referring to FIG. **10**, a block diagram of a cascaded inverter **1000** is shown in accordance with an illustrative embodiment. Cascaded inverter **1000** and capacitor **500** may be connected across V_{dc} **400** between positive DC line **402** and negative DC line **403** of third inverter **106c**, which may be grounded. Cascaded inverter **1000** may include a first inverter **106-1**, a second inverter **106-2**, . . . , and an mth inverter **106-m**. Cascaded inverter **1000** can include any number of m inverters subject to the power requirements of each electric machine **108** to which each inverter of cascaded inverter **1000** is connected. First inverter **106-1**, second inverter **106-2**, and mth inverter **106-m** may be any of first inverter **106a**, second inverter **106b**, and third inverter **106c**.

First inverter **106-1** includes first and second connector lines **1002a**, where the number of first and second connector lines **1002a** is a function of a number of phases supported by first inverter **106-1** as discussed previously. Second inverter **106-2** includes first and second connector lines **1002b**, where the number of first and second connector lines **1002a** is a function of a number of phases supported by second inverter **106-2** as discussed previously. mth inverter **106-m** includes first and second connector lines **1002m**, where the number of first and second connector lines **1002m** is a function of a number of phases supported by mth inverter **106-m** as discussed previously.

Various winding configurations may be suitable for electric machine **108**. Referring to FIGS. **11A** and **12A**, two winding sets are shown for illustration. Electric machine **108** includes two sets of windings. Machine manufacturers usually connect machine windings in series, but the machine windings of existing machines can be disconnected and reconnected into several winding groups. In an illustrative embodiment, individual machine winding groups have the same gauge, number of turns, and configuration as conventional ones.

Referring to FIG. **11A**, a first winding configuration **1100** is shown in accordance with an illustrative embodiment for stator winding **206**. First winding configuration **1100** includes first stator winding **600a**, second stator winding **602a**, third stator winding **604a**, fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b** with each winding positioned in one of a plurality of slots **1102** of stator **204**. First winding configuration **1100** forms a three-phase, four-pole, and twelve slot (1 slot per pole per phase) winding configuration where the three-phase windings forming different poles are separated and have their own neutral points, first common neutral connector **606a** and second common neutral connector **606b**.

Referring to FIG. **11B**, first winding configuration **1100** is shown in accordance with an illustrative embodiment distributed into portions of stator **204**. First stator winding **600a** and fourth stator winding **600b** are equally separated from each other by 180 degrees. Second stator winding **602a** and

fifth stator winding **602b** are equally separated from each other by 180 degrees. Third stator winding **604a** and sixth stator winding **604b** are equally separated from each other by 180 degrees. Each portion is approximately a 60 degree portion of stator **204**.

Referring to FIG. **12A**, a second winding configuration **1200** is shown in accordance with an illustrative embodiment for stator winding **206**. Second winding configuration **1200** includes first stator winding **600a**, second stator winding **602a**, third stator winding **604a**, fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b** with each winding positioned in one of the plurality of slots **1102** of stator **204**, but in different slots relative to first winding configuration **1100**.

Second winding configuration **1200** forms a three-phase, two-pole, and twelve slot (2 slots per pole per phase) winding configuration where the three-phase windings forming different poles are separated and have their own neutral points, first common neutral connector **606a** and second common neutral connector **606b**. If electric machine **108** has 2P poles with O slots per phase in each pole, the windings can be split into P·O segments. The windings can also be split into any factor of P·O segments, e.g., if P·O=6, the windings can be split into 1, 2, 3, or 6 segments.

Referring to FIG. **12B**, second winding configuration **1200** is shown in accordance with an illustrative embodiment distributed about portions of stator **204**. First stator winding **600a** and fourth stator winding **600b** are equally separated from each other by 60 degrees. Second stator winding **602a** and fifth stator winding **602b** are equally separated from each other by 60 degrees. Third stator winding **604a** and sixth stator winding **604b** are equally separated from each other by 60 degrees.

Referring to FIG. **13**, a third winding configuration **1300** is shown in accordance with an illustrative embodiment. Third winding configuration **1300** includes first stator winding **600a**, second stator winding **602a**, third stator winding **604a**, fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b** arranged to form a dual-voltage 9-lead electric machine.

Referring to FIG. **14**, a fourth winding configuration **1400** is shown in accordance with an illustrative embodiment for stator winding **206** in which third winding configuration **1300** has been disconnected and reconnected to form a first winding set **1402** and a second winding set **1404**. First winding set **1402** includes first stator winding **600a**, second stator winding **602a**, and third stator winding **604a**. Second winding set **1404** includes fourth stator winding **600b**, fifth stator winding **602b**, and sixth stator winding **604b**.

Because the described inverter circuits cancel the CM voltage, no CM electromagnetic interference filters are needed, resulting in an increased power density (6-25%), an increased system efficiency, and a reduced product cost. The ground leakage currents are further eliminated resulting in no interference with the control, gating, and protection circuits, which leads to increased system reliability. Use of the described inverter circuits further results in a prolonged motor life with reduced maintenance costs. Existing control algorithm, modulation, and sensing technologies are directly applicable to the new topology.

As used in this disclosure, the term “connect” includes join, unite, mount, couple, associate, insert, hang, hold, affix, attach, fasten, bind, paste, secure, bolt, screw, rivet, pin, nail, clasp, clamp, cement, fuse, solder, weld, glue, form over, slide together, layer, and other like terms. The phrases “connected on” and “connected to” include any interior or exterior portion of the element referenced.

Elements referenced as connected to each other herein may further be integrally formed together. As a result, elements described herein as being connected to each other need not be discrete structural elements. The elements may be connected permanently, removably, or releasably.

The word “illustrative” is used herein to mean serving as an example, instance, or illustration. Any aspect or design described herein as “illustrative” is not necessarily to be construed as preferred or advantageous over other aspects or designs. Further, for the purposes of this disclosure and unless otherwise specified, “a” or “an” means “one or more”. Still further, using “and” or “or” in the detailed description is intended to include “and/or” unless specifically indicated otherwise.

The foregoing description of illustrative embodiments of the disclosed subject matter has been presented for purposes of illustration and of description. It is not intended to be exhaustive or to limit the disclosed subject matter to the precise form disclosed, and modifications and variations are possible in light of the above teachings or may be acquired from practice of the disclosed subject matter. The embodiments were chosen and described in order to explain the principles of the disclosed subject matter and as practical applications of the disclosed subject matter to enable one skilled in the art to utilize the disclosed subject matter in various embodiments and with various modifications as suited to the particular use contemplated. It is intended that the scope of the disclosed subject matter be defined by the claims appended hereto and their equivalents.

What is claimed is:

1. An inverter comprising:
 - a positive direct current (DC) line;
 - a negative DC line; and
 - a plurality of inverter legs, wherein each inverter leg comprises
 - a first switch;
 - a first switch control line connected to the first switch and configured to receive a first control signal to control an on or off state of the first switch;
 - a second switch;
 - a second switch control line connected to the second switch and configured to receive a second control signal to control an on or off state of the second switch;
 - a third switch;
 - a third switch control line connected to the third switch and configured to receive the first control signal to control an on or off state of the third switch;
 - a first connector line connected between the first switch and the second switch; and
 - a second connector line connected between the second switch and the third switch;
- wherein the first switch, the second switch, and the third switch are connected sequentially in series between the positive DC line and the negative DC line;
- wherein the first connector line is configured to be connected to a first winding of an electric machine;
- wherein the second connector line is configured to be connected to a second winding of the electric machine;
- wherein the second control signal is complementary to the first control signal.
2. The inverter of claim 1, wherein the plurality of inverter legs comprise a first inverter leg and a second inverter leg, wherein the first connector line of the first inverter leg and

13

the first connector line of the second inverter leg are configured to be connected to opposite ends of the first winding of the electric machine.

3. The inverter of claim 2, wherein the second connector line of the first inverter leg and the second connector line of the second inverter leg are configured to be connected to opposite ends of the second winding of the electric machine.

4. The inverter of claim 1, wherein the second switch is rated to support a maximum DC voltage, wherein the first switch and the third switch are rated to support half the maximum DC voltage.

5. The inverter of claim 1, wherein the plurality of inverter legs comprise a first inverter leg, a second inverter leg, and a third inverter leg, wherein the first connector line of the first inverter leg, the first connector line of the second inverter leg, and the first connector line of the third inverter leg are configured to be connected to respective ends of a first set of windings of the electric machine, wherein opposite ends of the first set of windings are connected to a common neutral connector to form a three-phase wye connection configuration.

6. The inverter of claim 5, wherein the second connector line of the first inverter leg, the second connector line of the second inverter leg, and the second connector line of the third inverter leg are configured to be connected to respective ends of a second set of windings of the electric machine, wherein opposite ends of the second set of windings are connected to a second common neutral connector to form a second three-phase wye connection configuration.

7. An electric machine drive comprising:

a controller comprising

a first control signal line; and

a second control signal line, wherein the controller is configured to generate a first control signal on the first control signal line and to generate a second control signal on the second control signal line, wherein the first control signal is complementary to the second control signal; and

a positive direct current (DC) line;

a negative DC line; and

an inverter comprising a plurality of inverter legs, wherein each inverter leg comprises

a first switch;

a first switch control line connecting the first control signal line to the first switch to receive the first control signal;

a second switch;

a second switch control line connecting the second control signal line to the second switch to receive the second control signal;

a third switch;

a third switch control line connecting the first control signal line to the third switch to receive the first control signal;

a first connector line connected between the first switch and the second switch; and

a second connector line connected between the second switch and the third switch;

wherein the first switch, the second switch, and the third switch are connected sequentially in series between the positive DC line and the negative DC line;

wherein the first connector line is configured to be connected to a first winding of an electric machine;

wherein the second connector line is configured to be connected to a second winding of the electric machine;

14

wherein the first control signal controls an on or off state of the first switch and the third switch together; wherein the second control signal controls an on or off state of the second switch.

8. The electric machine drive of claim 7, wherein the plurality of inverter legs comprises a first inverter leg and a second inverter leg, wherein the first connector line of the first inverter leg and the first connector line of the second inverter leg are configured to be connected to opposite ends of the first winding of the electric machine.

9. The electric machine drive of claim 8, wherein the second connector line of the first inverter leg and the second connector line of the second inverter leg are configured to be connected to opposite ends of the second winding of the electric machine.

10. The electric machine drive of claim 7, wherein the second switch is rated to support a maximum DC voltage, wherein the first switch and the third switch are rated to support half the maximum DC voltage.

11. The electric machine drive of claim 7, further comprising a second inverter comprising:

a second plurality of inverter legs, wherein each inverter leg of the second plurality of inverter legs comprises a fourth switch;

a fourth switch control line connecting a third control signal line to the fourth switch to receive a third control signal;

a fifth switch;

a fifth switch control line connecting a fourth control signal line to the fifth switch to receive a fourth control signal;

a sixth switch;

a sixth switch control line connecting the third control signal line to the sixth switch to receive the third control signal;

a third connector line connected between the fourth switch and the fifth switch; and

a fourth connector line connected between the fifth switch and the sixth switch;

wherein the fourth switch, the fifth switch, and the sixth switch are connected sequentially in series between the positive DC line and the negative DC line;

wherein the third connector line is configured to be connected to a third winding of the electric machine; wherein the fourth connector line is configured to be connected to a fourth winding of the electric machine;

wherein the third control signal controls an on or off state of the fourth switch and the sixth switch together;

wherein the fourth control signal controls an on or off state of the fifth switch;

wherein the controller further comprises

the third control signal line; and

the fourth control signal line,

wherein the controller is configured to generate the third control signal on the third control signal line and to generate the fourth control signal on the fourth control signal line, wherein the fourth control signal is complementary to the third control signal.

12. An electric machine system comprising:

a controller comprising

a first control signal line; and

a second control signal line, wherein the controller is configured to generate a first control signal on the first control signal line and to generate a second

15

control signal on the second control signal line, wherein the first control signal is complementary to the second control signal;

a positive direct current (DC) line;

a negative DC line;

an inverter comprising a plurality of inverter legs, wherein each inverter leg comprises

a first switch;

a first switch control line connecting the first control signal line to the first switch to receive the first control signal;

a second switch;

a second switch control line connecting the second control signal line to the second switch to receive the second control signal;

a third switch;

a third switch control line connecting the first control signal line to the third switch to receive the first control signal;

a first connector line connected between the first switch and the second switch; and

a second connector line connected between the second switch and the third switch;

wherein the first switch, the second switch, and the third switch are connected sequentially in series between the positive DC line and the negative DC line;

wherein the first control signal controls an on or off state of the first switch the third switch together;

wherein the second control signal controls an on or off state of the second switch; and

an electric machine comprising

a stator;

a rotor configured to rotate relative to the stator;

a first winding wound around at least a first portion of the stator; and

a second winding wound around at least a second portion of the stator;

wherein the first connector line is configured to be connected to the first winding;

wherein the second connector line is configured to be connected to the second winding.

13. The electric machine system of claim 12, wherein the plurality of inverter legs comprises a first inverter leg and a second inverter leg, wherein the first connector line of the first inverter leg and the first connector line of the second inverter leg are configured to be connected to opposite ends of the first winding.

14. The electric machine system of claim 13, wherein the second connector line of the first inverter leg and the second connector line of the second inverter leg are configured to be connected to opposite ends of the second winding.

15. The electric machine system of claim 12, wherein the second switch is rated to support a maximum DC voltage, wherein the first switch and the third switch are rated to support half the maximum DC voltage.

16. The electric machine system of claim 12, wherein the electric machine further comprises:

a third winding wound around at least a third portion of the stator;

a fourth winding wound around at least a fourth portion of the stator;

16

a fifth winding wound around at least a fifth portion of the stator;

a sixth winding wound around at least a sixth portion of the stator;

wherein the first winding, the third winding, and the fifth winding are connected at a first end to a first common neutral connector,

wherein the second winding, the fourth winding, and the sixth winding are connected at a first end to a second common neutral connector,

wherein the plurality of inverter legs comprises a first inverter leg, a second inverter leg, and a third inverter leg;

wherein the first connector line of the first inverter leg is connected to a second end of the first winding opposite the first end;

wherein the first connector line of the second inverter leg is connected to a second end of the third winding opposite the first end;

wherein the first connector line of the third inverter leg is connected to a second end of the fifth winding opposite the first end;

wherein the second connector line of the first inverter leg is connected to a second end of the second winding opposite the first end;

wherein the second connector line of the second inverter leg is connected to a second end of the fourth winding opposite the first end;

wherein the second connector line of the third inverter leg is connected to a second end of the sixth winding opposite the first end.

17. The electric machine system of claim 16, wherein the first, third, and fifth portions of the stator are equally separated from the second, fourth, and sixth portions of the stator, respectively.

18. The electric machine system of claim 16, wherein the first, third, and fifth portions of the stator are respectively separated from the second, fourth, and sixth portions of the stator by 180 degrees.

19. The electric machine system of claim 16, wherein the electric machine further comprises:

a seventh winding wound around at least a seventh portion of the stator;

an eighth winding wound around at least an eighth portion of the stator;

wherein the seventh winding is further connected at a first end to the first common neutral connector,

wherein the eighth winding is further connected at a first end to the second common neutral connector,

wherein the plurality of inverter legs further comprises a fourth inverter leg;

wherein the first connector line of the fourth inverter leg is connected to a second end of the seventh winding opposite the first end;

wherein the second connector line of the fourth inverter leg is connected to a second end of the eighth winding opposite the first end.

20. The electric machine system of claim 12, wherein, when the electric machine is operated, a first current flowing through the first winding is 180 degrees out of phase relative to a second current flowing through the second winding.

* * * * *
